CHAPTER 1

Factoring Polynomials and Polynomial Equations

Chapter Outline

1.1 POLYNOMIAL EQUATIONS IN FACTORED FORM

1.2 FACTORING QUADRATIC EXPRESSIONS AND SOLVING QUADRATIC EQUATIONS BY FACTORING

1.3 FACTORING SPECIAL PRODUCTS AND SOLVING QUADRATIC EQUATIONS BY FACTORING

1.4 FACTORING POLYNOMIALS COMPLETELY AND SOLVING POLYNOMIAL EQUATIONS BY FACTORING
Learning Objectives

• Use the zero-product property
• Find greatest common monomial factor
• Solve simple polynomial equations by factoring

Introduction

Previously, we learned how to multiply polynomials. We did that by using the Distributive Property. All the terms in one polynomial must be multiplied by all terms in the other polynomial. In this section, you will start learning how to do this process in reverse. Similar to what you have done in the past with positive integers, the factors of 15 are 1, 3, 5, and 15 since:

1 \times 15 = 15
3 \times 5 = 15

The factors are the parts of multiplication problem. In this section you will be breaking down polynomials into the multiplication parts or factors. This process is called factoring polynomials.
Let's look at the areas of the rectangles again: Area = length \cdot width. The total area of the figure on the right can be found in two ways.

Method 1 Find the areas of all the small rectangles and add them
- Blue rectangle = \(ab\)
- Orange rectangle = \(ac\)
- Red rectangle = \(ad\)
- Green rectangle = \(ae\)
- Pink rectangle = \(2a\)

Total area = \(ab + ac + ad + ae + 2a\)

Method 2 Find the area of the big rectangle all at once

Length = \(a\)
Width = \(b + c + d + e + 2\)
Area = \(a(b + c + d + e + 2)\)

Since the area of the rectangle is the same no matter what method you use then the answers are the same:

\[ab + ac + ad + ae + 2a = a(b + c + d + e + 2)\]

**Factoring out the greatest common factor (GCF)** means that you take the factors that are common to all the terms in a polynomial. Then, multiply them by a parenthesis containing all the terms that are left over when you divide out the common factors.

**Use the Zero-Product Property**

Polynomials can be written in **expanded form** or in **factored form**. Expanded form means that you have sums and differences of different terms:
6x^4 + 7x^3 - 26x^2 + 17x + 30

Notice that the degree of the polynomials is four. It is written in standard form because the terms are written in order of decreasing power.

Factored form means that the polynomial is written as a product of factors. The factors are also polynomials, usually of lower degree.

\[ 6x^4 + 7x^3 - 26x^2 + 17x + 30 = (x - 1)(x + 2)(2x - 3)(3x + 5) \]

Factored form of a polynomial expression:

\[
\begin{array}{c}
(x - 1) \\
(\text{1st factor}) \\
(\text{2nd factor}) \\
(2x - 3) \\
(\text{3rd factor}) \\
(3x + 5) \\
(\text{4th factor})
\end{array}
\]

Notice that each factor in this polynomial is a binomial. Writing polynomials in factored form is very useful because it helps us solve polynomial equations. Before we talk about how we can solve polynomial equations of degree 2 or higher, let’s review how to solve a linear equation (degree 1).

**Example 1**

_Solve the following equations_

a) \[ x - 4 = 0 \]

\[
\begin{align*}
    x - 4 &= 0 \\
    +4 &= +4 \\
    x &= 4
\end{align*}
\]

b) \[ 3x - 5 = 0 \]

\[
\begin{align*}
    3x - 5 &= 0 \\
    +5 &= +5 \\
    3x &= 5 \\
    \frac{3x}{3} &= \frac{5}{3} \\
    x &= \frac{5}{3}
\end{align*}
\]

Now we are ready to think about solving equations like

\[ 2x^2 + 5x = 42 \]

Notice we can’t isolate \( x \) in any way that you have already learned. But, we can subtract 42 on both sides to get
\[ 2x^2 + 5x - 42 = 0 \]

Now, the left hand side of this equation can be factored!

Factoring a polynomial allows us to break up the problem into easier chunks. For example,

\[ 2x^2 + 5x - 42 = (x + 6)(2x - 7) \]

So now we want to solve:

\[ (x + 6)(2x - 7) = 0 \]

How would we solve this? If we multiply two numbers together and their product is zero, what can we say about these numbers? The only way a product is zero is if one or both of the terms are zero. This property is called the **Zero-product Property** and is the property used to solve factorable polynomials. In general, if

\[
\text{If} \quad a \times b = 0 \quad \text{then} \quad a = 0 \quad \text{OR} \quad b = 0
\]

How does that help us solve the polynomial equation? Since the product equals 0, then either of the terms or factors in the product must equal zero. We set each factor equal to zero and we solve. You will learn the factoring process later in this chapter.

\[ (x + 6) = 0 \quad \text{OR} \quad (2x - 7) = 0 \]

We can now solve each part individually and we obtain:

\[
\begin{align*}
x + 6 &= 0 & \quad \text{or} & \quad 2x - 7 &= 0 \\
x &= -6 & \quad \text{or} & \quad 2x &= 7 \\
& & \quad \text{or} & \quad x &= \frac{7}{2}
\end{align*}
\]

Notice that the solution is \( x = -6 \) **OR** \( x = \frac{7}{2} \). The **OR** says that either of these values of \( x \) would make the product of the two factors equal to zero. Lets plug the solutions back into the equation and check that this is correct.
Check $x = -6$
\[(x + 6)(2x - 7) =
\]^2
\[(-6 + 6)(2(6) - 7) =
\]^2
\[(0)(5) = 0
\]

Check $x = \frac{7}{2}$
\[(x + 6)(2x - 7) =
\][7 + 6]
\[\left(\frac{7}{2}\right) \left(\frac{7}{2} - 7\right) =
\][19]
\[\left(\frac{19}{2}\right)(7 - 7) =
\][19]
\[\left(\frac{19}{2}\right)(0) = 0
\]

We can also substitute the solutions back into the original equation $2x^2 + 5x = 42$.

Check $x = -6$
\[2(-6)^2 + 5(-6) = 42 =
\][36]
\[2(36) + (-30) = 42 =
\][72]
\[72 + (-30) = 42
\]
\[42 = 42
\]

Check $x = \frac{7}{2}$
\[2\left(\frac{7}{2}\right)^2 + 5\left(\frac{7}{2}\right) = 42
\][49]
\[2\left(\frac{49}{4}\right) + 5\left(\frac{7}{2}\right) = 42
\][49]
\[\frac{49}{2} + \frac{35}{2} = 42
\][84]
\[\frac{84}{2} = 42
\]
\[42 = 42
\]

Both solutions check out. You should notice that the product equals to zero because each solution makes one of the factors simplify to zero.

If we are not able to factor a polynomial the problem becomes harder and we must use other methods that you will learn later.

As a last note in this section, keep in mind that the Zero-product Property only works when a product equals zero. For example, if you multiplied two numbers and the answer was nine you could not say that each of the numbers was nine.
In order to use the property, you must have the factored polynomial equal to zero.

\[(x + 2)(x - 3) = 0\]  
\[x = -2 \text{ or } x = 3\]

**Example 2**

Solve each of the polynomials

a) \((x - 9)(3x + 4) = 0\)
b) \(x(5x - 4) = 0\)
c) \(4x(x + 6)(4x - 9) = 0\)

**Solution**

Since all polynomials are in factored form, we set each factor equal to zero and solve the simpler equations separately

a) \((x - 9)(3x + 4) = 0\) can be split up into two linear equations

\[x - 9 = 0 \quad \text{or} \quad 3x + 4 = 0\]

\[x = 9 \quad \text{or} \quad 3x = -4\]

\[x = 9 \quad \text{or} \quad x = -\frac{4}{3}\]

b) \(x(5x - 4) = 0\) can be split up into two linear equations

\[x = 0 \quad \text{or} \quad 5x - 4 = 0\]

\[x = 0 \quad \text{or} \quad 5x = 4\]

\[x = 0 \quad \text{or} \quad x = \frac{4}{5}\]

c) \(4x(x + 6)(4x - 9) = 0\) can be split up into three linear equations.

\[4x = 0 \quad \text{or} \quad 4x - 9 = 0\]

\[4x = 0 \quad \text{or} \quad 4x = 9\]

\[x = \frac{0}{4} \quad \text{or} \quad x + 6 = 0\]

\[x = 0 \quad \text{or} \quad x = -6\]

\[x = \frac{9}{4}\]

**Find Greatest Common Monomial Factor**

Once we get a polynomial in factored form, it is easier to solve the polynomial equation. But first, we need to learn how to factor. There are several factoring methods you will be learning in the next few sections. In most cases,
1.1. Polynomial Equations in Factored Form

factoring can take several steps to complete because we want to factor completely. That means that we factor until we cannot factor anymore.

Let's start with the simplest case, finding the greatest common factor or GCF. When we want to factor, we always look for common monomials first. Consider the following polynomial, written in expanded form.

\[ ax + bx + cx + dx \]

A common factor can be a number, a variable or a combination of numbers and variables that are contained in all terms of the polynomial. We are looking for expressions that divide out evenly from each term in the polynomial. Notice that in our example, the factor \( x \) appears in all terms. Therefore \( x \) is a common factor.

\[ x \cdot (a) + x \cdot (b) + x \cdot (c) + x \cdot (d) \]

Since \( x \) is a common factor, we factor it by writing to the left of a set of parenthesis:

\[ x ( ) \]

Inside the parenthesis, we write what is left over when we divide or factor out \( x \) from each term.

\[ x(a + b + c + d) \]

Let's look at more examples.

**Example 3**

**Factor**

\begin{align*}
a) & \quad 2x + 8 \\
b) & \quad 15x - 25 \\
c) & \quad 3a + 9b + 6
\end{align*}

**Solution**

\begin{align*}
a) & \quad \text{We see that the factor 2 divides evenly from both terms.} \\
& \quad 2x + 8 = 2(x) + 2(4) \\
& \quad \text{We factor the 2 by writing it to the left of a parenthesis.} \\
& \quad 2( ) \\
& \quad \text{Inside the parenthesis, we write what is left from each term when we divide by 2 or factor out 2.} \\
& \quad 2(x + 4) \text{ This is the factored form.} \\
b) & \quad \text{We see that the factor of 5 divides evenly from all terms.} \\
& \quad \text{Rewrite } 15x - 25 = 5(3x) - 5(5). \\
& \quad \text{Factor 5 to get } 5(3x - 5). \\
c) & \quad \text{We see that the factor of 3 divides evenly from all terms.} \\
& \quad \text{Rewrite } 3a + 9b + 6 = 3(a) + 3(3b) + 3(2) 
\end{align*}
Factor 3 to get $3(a + 3b + 2)$.

Here are examples where different powers of the common factor appear in the polynomial.

**Example 4**

*Find the greatest common factor*

a) $a^3 - 3a^2 + 4a$
b) $12a^4 - 5a^3 + 7a^2$

**Solution**

a) $a^3 - 3a^2 + 4a$

Notice that $a$ appears in all terms of $a^3 - 3a^2 + 4a$ but each term has a different power of $a$. The common variable factor is the lowest power of the variable that appears in each term of the expression. In this case the common factor is $a$.

Let's rewrite $a^3 - 3a^2 + 4a = a(a^2) + a(-3a) + a(4)$

Factor $a$ to get $a(a^2 - 3a + 4)$.

b) $12a^4 - 5a^3 + 7a^2$

The factor $a$ appears in all the term and the lowest power is $a^2$.

We rewrite the expression as $12a^4 - 5a^3 + 7a^2 = 12a^2 \cdot a^2 - 5a \cdot a^2 + 7 \cdot a^2$

Factor $a^2$ to get $a^2(12a^2 - 5a + 7)$

Lets look at some examples where there is more than one common factor.

**Example 5:**

*Factor completely*

a) $3ax + 9a$
b) $x^3y + xy$
c) $5x^3y - 15x^2y^2 + 25xy^3$

**Solution**

a) Notice that 3 is common to both terms.

When we factor 3 we get $3(ax + 3a)$

This is not completely factored though because if you look inside the parenthesis, we notice that $a$ is also a common factor.

When we factor $a$ we get $3 \cdot a(x + 3)$, which is equivalent to $3a(x + 3)$.

This is the final answer because there are no more common factors.

A different option is to factor all common factors at once.

Since both 3 and $a$ are common we factor the term $3a$ and get $3a(x + 3)$.

b) Notice that both $x$ and $y$ are common factors.

Let's rewrite the expression $x^3y + xy = xy(x^2) + xy(1)$

When we factor $xy$ we obtain $xy(x^2 + 1)$.

c) The common factors are $5xy$.

When we factor $5xy$ we obtain $5xy(x^2 - 3xy + 5y^2)$. 
Note: Always look for both the common number and variable factors for each term in the expression.

**Solve Simple Polynomial Equations by Factoring**

Now that we know the basics of factoring, we can solve some simple polynomial equations. We already saw how we can use the Zero-product Property to solve polynomials in factored form. Here you will learn how to solve polynomials in expanded form. These are the steps for this process.

**Step 1**
If necessary, **re-write** the equation in standard form such that:
Polynomial expression = 0.

**Step 2**
**Factor** the polynomial completely.

**Step 3**
Use the zero-product rule to set each factor equal to zero.

**Step 4**
Solve each equation from step 3.

**Step 5**
**Check** your answers by substituting your solutions into the original equation.

**Example 6**

*Solve the following polynomial equations*

a) \( x^2 - 2x = 0 \)

b) \( 2x^2 = 5x \)

c) \( 9x^2 - 6x = 0 \)

**Solution:**

a) \( x^2 - 2x = 0 \)

**Rewrite.** This is not necessary since the equation is in the standard form.

**Factor.** The common factor is \( x \), so this factors as: \( x(x - 2) = 0 \).

**Set each factor equal to zero.**

\[
\begin{align*}
    x &= 0 \quad \text{or} \quad x - 2 = 0 \\
\end{align*}
\]

**Solve.**

\[
\begin{align*}
    x &= 0 \quad \text{or} \quad x = 2 \\
\end{align*}
\]

**Check** Substitute each solution back into the original equation.

\[
\begin{align*}
    x = 0 & \quad \Rightarrow \quad (0)^2 - 2(0) = 0 & \text{check} \\
    x = 2 & \quad \Rightarrow \quad (2)^2 - 2(2) = 4 - 4 = 0 & \text{check}
\end{align*}
\]
b) \(2x^2 = 5x\)

Rewrite. \(2x^2 = 5x \Rightarrow 2x^2 - 5x = 0\).

Factor. The common factor is \(x\), so this factors as: \(x(2x - 5) = 0\).

Set each factor equal to zero.

\[
x = 0 \quad \text{or} \quad 2x - 5 = 0
\]

Solve.

\[
x = 0 \quad \text{or} \quad 2x = 5 \Rightarrow x = \frac{5}{2}
\]

Check. Substitute each solution back into the original equation.

\[
x = 0 \Rightarrow 2(0)^2 = 5(0) \Rightarrow 0 = 0 \quad \text{works out}
\]
\[
x = \frac{5}{2} \Rightarrow 2 \left( \frac{5}{2} \right)^2 = 5 \cdot \frac{5}{2} \Rightarrow 2 \cdot \frac{25}{4} = \frac{25}{2} \Rightarrow \frac{25}{2} = \frac{25}{2} \quad \text{works out}
\]

Answer

\[
x = 0 \quad \text{or} \quad x = \frac{5}{2}
\]

c) \(9x^2 - 6x = 0\)

Rewrite. This step is not necessary.

Factor. The common factor is \(3x\), so this factors as \(3x(3x - 2) = 0\).

Set each factor equal to zero.

\[
3x = 0 \quad \text{or} \quad 3x - 2 = 0
\]

Solve.

\[
x = 0 \quad \text{or} \quad 3x = 2 \Rightarrow x = \frac{2}{3}
\]

Check. Substitute each solution back into the original equation.
\[ x = 0 \Rightarrow 9(0) - 6(0) = 0 - 0 = 0 \quad \text{checks} \]

\[ x = \frac{2}{3} \Rightarrow 9 \cdot \left(\frac{2}{3}\right)^2 - 6 \cdot \frac{2}{3} = 9 \cdot \frac{4}{9} - 4 = 4 - 4 = 0 \quad \text{checks} \]

**Answer**

\[ x = 0 \quad \text{or} \quad x = \frac{2}{3} \]
1.2 Factoring Quadratic Expressions and Solving Quadratic Equations by Factoring

Learning Objectives

- Write quadratic equations in standard form.
- Factor quadratic expressions.
- Factor quadratic expression when the leading coefficient is -1.
- Solve polynomial equations by factoring.

Write Quadratic Expressions in Standard Form

Quadratic polynomials are polynomials of degree 2. The standard form of a quadratic polynomial is written as

\[ ax^2 + bx + c \]

Here \( a, b, \) and \( c \) stand for constant numbers. Factoring these polynomials depends on the values of these constants. In this section, we will learn how to factor quadratic polynomials for different values of \( a, b, \) and \( c. \) In the last section, we factored out common monomials, so you already know how to factor quadratic polynomials where \( c = 0. \)

For example for the quadratic \( ax^2 + bx, \) the common factor is \( x \) and this expression is factored as \( x(ax + b). \) When all the coefficients are not zero these expressions are also called Quadratic Trinomials, since they are polynomials with three terms.

Factor when \( a = 1, b \) is Positive, and \( c \) is Positive

Lets first consider the case where \( a = 1, b \) is positive and \( c \) is positive. The quadratic trinomials will take the following form.

\[ x^2 + bx + c \]

You know from multiplying binomials that when you multiply two factors \((x + m)(x + n)\) you obtain a quadratic polynomial. Lets multiply this and see what happens. We use The Distributive Property.

\[(x + m)(x + n) = x^2 + nx + mx + mn\]

Multiplying two binomials is sometime referred to as FOIL. The letters of the word FOIL can be used to help remember the four products when multiplying to binomials.

\[ F \rightarrow First \]
\[ O \rightarrow Outer \]
\[ I \rightarrow Inner \]
\[ L \rightarrow Last \]
1. Find the product of the **first** terms of the two binomials.
2. Find the product of the **outer** terms of the two binomials.
3. Find the product of the **inner** terms of the two binomials.
4. Find the product of the **last** terms of the two binomials.

Yet, another way to multiply two binomials is to think of double distribution. Distribute the first term of the first binomial to the second binomial. The distribute the second term of the first binomial to the second binomial.

To simplify this polynomial we would combine the like terms in the middle by adding them.

\[(x + m)(x + n) = x^2 + (n + m)x + mn\]

To factor we need to do this process in reverse.

We see that \(x^2 + (n + m)x + mn\) is the same form as \(x^2 + bx + c\).

This means that we need to find two numbers \(m\) and \(n\) where

\[n + m = b\] and \[mn = c\]

To factor \(x^2 + bx + c\), the answer is the product of two parentheses.

\((x + m)(x + n)\)

so that \(n + m = b\) and \(mn = c\).

Let's try some specific examples.

**Example 1**

*Factor \(x^2 + 5x + 6\)*

**Solution** We are looking for an answer that is a product of two binomials in parentheses.

\[(x + \underline{\hspace{1cm}})(x + \underline{\hspace{1cm}})\]

To fill in the blanks, we want two numbers \(m\) and \(n\) that multiply to 6 and add to 5. A good strategy is to list the possible ways we can multiply two numbers to give us 6 and then see which of these pairs of numbers add to 5. The number six can be written as the product using its factors.

\[6 = 1 \cdot 6 \quad \text{and} \quad 1 + 6 = 7\]
\[6 = 2 \cdot 3 \quad \text{and} \quad 2 + 3 = 5\]

← This is the correct choice.

So the answer is \((x + 2)(x + 3)\).

We can check to see if this is correct by multiplying \((x + 2)(x + 3)\).

\[(x + 2)(x + 3) = x^2 + 3x + 2x + 6 = x^2 + 5x + 6\]
The answer checks out.

Example 2

Factor $x^2 + 7x + 12$

Solution

We are looking for an answer that is a product of two parentheses $(x + \_)(x + \_)$.

The number 12 can be written as the product of the following numbers.

\[
\begin{align*}
12 &= 1 \cdot 12 \\
12 &= 2 \cdot 6 \\
12 &= 3 \cdot 4
\end{align*}
\]

\[
\begin{align*}
1 + 12 &= 13 \\
2 + 6 &= 8 \\
3 + 4 &= 7
\end{align*}
\]

← This is the correct choice.

The answer is $(x + 3)(x + 4)$. When these factors are multiplied, the product is $x^2 + 7x + 12$.

Example 3

Factor $x^2 + 8x + 12$.

Solution

We are looking for the product of the two binomials in parentheses $(x + \_)(x + \_)$.

The number 12 can be written as the product of the following numbers.

\[
\begin{align*}
12 &= 1 \cdot 12 \\
12 &= 2 \cdot 6 \\
12 &= 3 \cdot 4
\end{align*}
\]

\[
\begin{align*}
1 + 12 &= 13 \\
2 + 6 &= 8 \\
3 + 4 &= 7
\end{align*}
\]

← This is the correct choice.

The answer is $(x + 2)(x + 6)$. When these factors are multiplied, the product is $x^2 + 8x + 12$.

Example 4

Factor $x^2 + 12x + 36$.

Solution

We are looking for the product of the two binomials in parentheses $(x + \_)(x + \_)$.

The number 36 can be written as the product of the following numbers.

\[
\begin{align*}
36 &= 1 \cdot 36 \\
36 &= 2 \cdot 18 \\
36 &= 3 \cdot 12 \\
36 &= 4 \cdot 9 \\
36 &= 6 \cdot 6
\end{align*}
\]

\[
\begin{align*}
1 + 36 &= 37 \\
2 + 18 &= 20 \\
3 + 12 &= 15 \\
4 + 9 &= 13 \\
6 + 6 &= 12
\end{align*}
\]

← This is the correct choice.

The answer is $(x + 6)(x + 6)$. When these factors are multiplied, the product is $x^2 + 12x + 36$.

**Factor when a = 1, b is Negative and c is Positive**

Now let's see how this method works if the middle coefficient ($b$) is negative.
Example 5

*Factor* $x^2 - 6x + 8$.

**Solution**

We are looking for the product of the two binomials in parentheses $(x + _) (x + _)$. The number 8 can be written as the product of the following numbers:

- $8 = (1) \cdot (8)$ and $1 + (8) = 9$
- $8 = (-1) \cdot (-8)$ and $-1 + (-8) = -9$
- $8 = 2 \cdot 4$ and $2 + 4 = 6$
- $8 = (-2) \cdot (-4)$ and $-2 + (-4) = -6$

$8 = (-2) \cdot (-4)$ and $-2 + (-4) = -6$ ← This is the correct choice.

The factorization is $(x + (-2))(x + (-4))$ and this can be written as $(x - 2)(x - 4)$.

The answer is $(x - 2)(x - 4)$.

We can check to see if this is correct by multiplying $(x - 2)(x - 4)$.

$$(x - 2)(x - 4) = x^2 - 2x - 4x + 8 = x^2 - 6x + 8$$

The answer checks out.

Example 6

*Factor* $x^2 - 17x + 16$

**Solution**

We are looking for the product of two binomials in parentheses. We will use $\pm$ to mean plus or minus. $(x \pm _ _) (x \pm _ _)$. The number 16 can be written as the product of the following numbers:

- $16 = 1 \cdot 16$ and $1 + 16 = 17$
- $16 = (-1) \cdot (-16)$ and $-1 + (-16) = -17$ ← This is the correct choice.
- $16 = 2 \cdot 8$ and $2 + 8 = 10$
- $16 = (-2) \cdot (-8)$ and $-2 + (-8) = -10$
- $16 = 4 \cdot 4$ and $4 + 4 = 8$
- $16 = (-4) \cdot (-4)$ and $-4 + (-4) = -8$

The answer is $(x - 1)(x - 16)$. When these factors are multiplied, the product is $x^2 - 17x + 16$.

Note: When the correct choice of factors are found, there is no need to continue the trial and error process to find the factors of $c$ that add to $b$. 
Factor when \(a = 1\) and \(c\) is Negative

Now let's see how this method works if the constant term is negative.

Example 7

*Factor* \(x^2 + 2x - 15\)

**Solution**

We are looking for the product of two binomials in parentheses \((x \pm \_)(x \pm \_)\).

In this case, we must take the negative sign into account. The number -15 can be written as the product of the following numbers.

\[-15 = -1 \cdot 15 \quad \text{and} \quad -1 + 15 = 14 \quad \text{Notice that these are two different choices.}\]

\[-15 = 1 \cdot (-15) \quad \text{and} \quad 1 + (-15) = -14 \quad \text{Notice that these are two different choices.}\]

\[-15 = -3 \cdot 5 \quad \text{and} \quad -3 + 5 = 2 \quad \leftarrow \quad \text{This is the correct choice.}\]

\[-15 = 3 \cdot (-5) \quad \text{and} \quad 3 + (-5) = -2\]

The answer is \((x - 3)(x + 5)\).

We can check to see if this is correct by multiplying \((x - 3)(x + 5)\).

\[ (x - 3)(x + 5) = x^2 - 3x + 5x - 15 = x^2 + 2x - 15 \]

The answer checks out.

Example 8

*Factor* \(x^2 - 10x - 24\)

**Solution**

We are looking for the product of two binomials in parentheses \((x \pm \_)(x \pm \_)\).

The number -24 can be written as the product of the following numbers.

\[-24 = -1 \cdot 24 \quad \text{and} \quad -1 + 24 = 23\]

\[-24 = 1 \cdot (-24) \quad \text{and} \quad 1 + (-24) = -23\]

\[-24 = -2 \cdot 12 \quad \text{and} \quad -2 + 12 = 10\]

\[-24 = 2 \cdot (-12) \quad \text{and} \quad 2 + (-12) = -10 \quad \leftarrow \quad \text{This is the correct choice.}\]

\[-24 = -3 \cdot 8 \quad \text{and} \quad -3 + 8 = 5\]

\[-24 = 3 \cdot (-8) \quad \text{and} \quad 3 + (-8) = -5\]

\[-24 = -4 \cdot 6 \quad \text{and} \quad -4 + 6 = 2\]

\[-24 = 4 \cdot (-6) \quad \text{and} \quad 4 + (-6) = -2\]
The answer is 

\((x - 12)(x + 2)\). We can verify this is the correct factorization by multiplying the binomials.

**Example 9**

Factor \(x^2 + 34x - 35\)

**Solution**

We are looking for the product of two binomials in parentheses \((x \pm \_\_\_)(x \pm \_\_\_)\).

The number -35 can be written as the product of the following numbers:

\[
-35 = -1 \cdot 35 \quad \text{and} \quad -1 + 35 = 34 \quad \leftarrow \quad \text{This is the correct choice.}
\]
\[
-35 = 1 \cdot (-35) \quad \text{and} \quad 1 + (-35) = -34
\]
\[
-35 = -5 \cdot 7 \quad \text{and} \quad -5 + 7 = 2
\]
\[
-35 = 5 \cdot (-7) \quad \text{and} \quad 5 + (-7) = -2
\]

The answer is \((x - 1)(x + 35)\).

**Factor when \(a = -1\)**

When \(a = -1\), the best strategy is to factor the common factor of -1 from all the terms in the quadratic polynomial. Then, you can apply the methods you have learned so far in this section to find the missing factors.

**Example 10**

Factor \(-x^2 + x + 6\).

**Solution**

First factor the common factor of -1 from each term in the trinomial. Factoring -1 changes the signs of each term in the expression.

\[-x^2 + x + 6 = -(x^2 - x - 6)\]

We are looking for the product of two binomials in parentheses \((x \pm \_\_\_)(x \pm \_\_\_)\).

Now our job is to factor \(x^2 - x - 6\).

The number -6 can be written as the product of the following numbers:

\[
-6 = -1 \cdot 6 \quad \text{and} \quad -1 + 6 = 5
\]
\[
-6 = 1 \cdot (-6) \quad \text{and} \quad 1 + (-6) = -5
\]
\[
-6 = -2 \cdot 3 \quad \text{and} \quad -2 + 3 = 1
\]
\[
-6 = 2 \cdot (-3) \quad \text{and} \quad 2 + (-3) = -1 \quad \leftarrow \quad \text{This is the correct choice.}
\]

The answer is \(-(x - 3)(x + 2)\).

**Solve Quadratic Equations by Factoring**

Now that we know the basics of factoring, we can solve some simple polynomial equations. We already saw how we can use the Zero-product Property to solve polynomials in factored form. However, it is important to recognize the different between an expression and an equation.
This is a quadratic expression: \( ax^2 + bx + c \)
This is a quadratic equation: \( ax^2 + bx + c = 0 \)

The degree of an equation determines the most number of solutions that the equation could have. Since we will be solving quadratic equations, which are equations of degree 2, we can expect two solutions. However, one solution can be a repeated solution. For example, \((x + 3)(x + 3) = 0\) has a solution of \(x = -3\), but this is a repeated solution because the quadratic equation has two factors of \((x + 3)\).

Now we will learn how to solve factorable quadratic equations in expanded form.

**Steps to Solving Quadratic Equations in Factored Form**

**Step 1**
If necessary, **re-write** the equation in standard form such that:
Polynomial expression \( = 0 \).

**Step 2**
**Factor** the quadratic completely.

**Step 3**
Use the zero-product rule to set each factor equal to zero.

**Step 4**
**Solve** each equation from step 3.

**Step 5**
**Check** your answers by substituting your solutions into the original equation.

**Example 11**

_Solve the following polynomial equations_

a) \( x^2 - 2x - 15 = 0 \)

b) \( x^2 = 5x + 6 \)

c) \( -x^2 = 8 - 6x \)

**Solution:**
a) \( x^2 - 2x - 15 = 0 \)

**Rewrite.** This is not necessary since the equation is in the correct form.

**Factor** \((x - 5)(x + 3) = 0\).

**Set each factor equal to zero.**

\[ x - 5 = 0 \quad \text{or} \quad x + 3 = 0 \]

**Solve.**

\[ x = 5 \quad \text{or} \quad x = -3 \]

**Check.** Substitute each solution back into the original equation.
\[ x = 5 \quad \Rightarrow \quad (5)^2 - 2(5) - 15 = 0 \quad \text{check} \]
\[ x = -3 \quad \Rightarrow \quad (-3)^2 - 2(-3) - 15 = 0 \quad \text{check} \]

**Answer** \( x = 5, x = -3 \)

b) \( x^2 = 5x + 6 \)

**Rewrite** \( x^2 - 5x - 6 = 0 \).

**Factor** \((x - 6)(x + 1) = 0\).

Set each factor equal to zero.

\[ x - 6 = 0 \quad \text{or} \quad x + 1 = 0 \]

**Solve**

\[ x = 6 \quad \text{or} \quad x = -1 \]

**Check** Substitute each solution back into the original equation.

\[ x = 6 \quad \Rightarrow \quad (6)^2 - 5(6) - 6 = 0 \quad \text{check} \]
\[ x = -1 \quad \Rightarrow \quad (-1)^2 - 5(-1) - 6 = 0 \quad \text{check} \]

**Answer** \( x = 6, x = -1 \)

c) \(-x^2 = 8 - 6x\)

**Rewrite** \(-x^2 + 6x - 8 = 0\)

**Factor**

\[ -x^2 + 6x - 8 = 0 \quad \Rightarrow \quad -1(x^2 - 6x + 8) = 0 \quad \Rightarrow \quad -1(x - 4)(x - 2) = 0 \]

Set each factor equal to zero:

\[ x - 4 = 0 \quad \text{or} \quad x - 2 = 0 \]

**Solve**

\[ x = 4 \quad \text{or} \quad x = 2 \]

**Check** Substitute each solution back into the original equation.

\[ x = 4 \Rightarrow -(4)^2 + 6(4) - 8 = 0 \quad \text{works out} \]
\[ x = 2 \Rightarrow -(2)^2 + 6(2) - 8 = 0 \quad \text{works out} \]
Answer \( x = 4, x = 2 \)

To Summarize,

A quadratic of the form \( x^2 + bx + c \) factors as a product of two parenthesis \( (x + m)(x + n) \).

- If \( b \) and \( c \) are positive then both \( m \) and \( n \) are positive
  - Example: \( x^2 + 8x + 12 \) factors as \( (x + 6)(x + 2) \).
- If \( b \) is negative and \( c \) is positive then both \( m \) and \( n \) are negative.
  - Example: \( x^2 - 6x + 8 \) factors as \( (x - 2)(x - 4) \).
- If \( c \) is negative then either \( m \) is positive and \( n \) is negative or vice-versa
  - Example: \( x^2 + 2x - 15 \) factors as \( (x + 5)(x - 3) \).
  - Example: \( x^2 + 34x - 35 \) factors as \( (x + 35)(x - 1) \).
- If \( a = -1 \), factor a common factor of -1 from each term in the trinomial and then factor as usual. The answer will have the form \( -(x + m)(x + n) \).
  - Example: \(-x^2 + x + 6 \) factors as \( -(x - 3)(x + 2) \).

Concept Extension

Example 12

The solutions to a quadratic equation are \( x = -3 \) and \( x = 4 \). What was the original quadratic equation in standard form with a leading coefficient of 1?

Solution:

If a solution is \( x = -3 \), then a factor of the quadratic equation was \( (x + 3) \).

If a solution is \( x = 4 \), then a factor of the quadratic equation was \( (x - 4) \).

As a result the original quadratic equation with a leading coefficient of 1 would be:

\[
(x - 3)(x + 4) = 0
\]

Now multiply the left side and simplify.

\[
(x - 3)(x + 4) = 0 \\
x^2 - 3x + 4x - 12 = 0 \\
x^2 + x - 12 = 0
\]

Example 13

The solutions to a quadratic equation are \( x = \frac{3}{4} \) and \( x = -\frac{1}{5} \). What was a possible original quadratic equation in standard form?

Solution:

If a solution is \( x = \frac{3}{4} \), then a factor of the quadratic equation was \( (4x - 3) \).

If a solution is \( x = -\frac{1}{5} \), then a factor of the quadratic equation was \( (3x + 1) \).

As a result the original quadratic equation with a leading coefficient of 1 would be:
$(4x - 3)(3 + 1) = 0$

Now multiply the left side and simplify.

$(4x - 3)(3 + 1) = 0$
$12x^2 + 4x - 9x - 3 = 0$
$12x^2 - 5x - 3 = 0$
1.3 Factoring Special Products and Solving Quadratic Equations by Factoring

Learning Objectives

• Factor the difference of two squares.
• Factor perfect square trinomials.
• Factor the sum and difference of cubes.
• Solve quadratic polynomial equation by factoring.

Introduction

When you learned how to multiply binomials we talked about two special products.

\[ \text{The Sum and Difference Formula} \]
\[ a^2 - b^2 = (a + b)(a - b) \]

\[ \text{The Square of a Binomial Formula} \]
\[ a^2 + 2ab + b^2 = (a + b)^2 \]
\[ a^2 - 2ab + b^2 = (a - b)^2 \]

\[ \text{The Sum or Difference of Cubes Formula} \]
\[ a^3 + b^3 = (a + b)(a^2 - ab + b^2) \]
\[ a^3 - b^3 = (a - b)(a^2 + ab + b^2) \]

In this section we will learn how to recognize and factor these special products.

Factor the Difference of Two Squares

We use the sum and difference formula to factor a difference of two squares. A difference of two squares can be a quadratic polynomial in this form.

\[ a^2 - b^2 \]

Both terms in the polynomial are perfect squares. In a case like this, the polynomial factors into the sum and difference of the square root of each term.

\[ a^2 - b^2 = (a + b)(a - b) \]

In these problems, the key is figuring out what the \( a \) and \( b \) terms are. For review here is a table of perfect squares.

**Table 1.1: Perfect Squares**

1.3. Factoring Special Products and Solving Quadratic Equations by Factoring

Let's do some examples of this type.

**Example 1**

Factor the difference of squares.

a) \( x^2 - 9 \)

b) \( x^2 - 100 \)

c) \( x^2 - 1 \)

**Solution**

a) Rewrite as \( x^2 - 9 \) as \( x^2 - 3^2 \). Now it is obvious that it is a difference of squares.

The difference of squares formula is \( a^2 - b^2 = (a + b)(a - b) \).

Let's see how our problem matches with the formula \( x^2 - 3^2 = (x + 3)(x - 3) \).

The answer is \( x^2 - 9 = (x + 3)(x - 3) \).

We can check to see if this is correct by multiplying \((x + 3)(x - 3)\).

\[
(x + 3)(x - 3) = x^2 - 3x + 3x - 9 = x^2 - 9
\]

The product checks out.

We could factor this polynomial without recognizing that it is a difference of squares. With the methods we learned in the last section we know that a quadratic polynomial factors into the product of two binomials.

\[
(x \pm ____)(x \pm ____)
\]

We can think of \( x^2 - 9 \) as \( x^2 + 0x - 9 \) and use the same method we used in the last section.

We need to find two numbers that multiply to -9 and add to 0, since the middle term is missing.

We can write -9 as the following products

\[
\begin{align*}
-9 &= -1 \cdot 9 & \text{and} & -1 + 9 &= 8 \\
-9 &= 1 \cdot (-9) & \text{and} & 1 + (-9) &= -8 \\
-9 &= 3 \cdot (-3) & \text{and} & 3 + (-3) &= 0 \quad \leftarrow \quad \text{This is the correct choice}
\end{align*}
\]

We can factor \( x^2 - 9 \) as \( (x + 3)(x - 3) \), which is the same answer as before.

You can always factor using methods for factoring trinomials, but it is faster if you can recognize special products such as the difference of squares.

b) Rewrite \( x^2 - 100 \) as \( x^2 - 10^2 \). This factors as \( (x + 10)(x - 10) \).

c) Rewrite \( x^2 - 1 \) as \( x^2 - 1^2 \). This factors as \( (x + 1)(x - 1) \).

**Example 2**

Factor the difference of squares.

a) \( 16x^2 - 25 \)
b) $4x^2 - 81$

c) $49x^2 - 64$

**Solution**

a) Rewrite $16x^2 - 25$ as $(4x)^2 - 5^2$. This factors as $(4x + 5)(4x - 5)$.  

b) Rewrite $4x^2 - 81$ as $(2x)^2 - 9^2$. This factors as $(2x + 9)(2x - 9)$.  

c) Rewrite $49x^2 - 64$ as $(7x)^2 - 8^2$. This factors as $(7x + 8)(7x - 8)$.  

**Example 3**

*Factor the difference of squares:*  

a) $x^2 - y^2$

b) $9x^2 - 4y^2$

c) $x^2y^2 - 1$

**Solution**

a) $x^2 - y^2$ factors as $(x + y)(x - y)$.  

b) Rewrite $9x^2 - 4y^2$ as $(3x)^2 - (2y)^2$. This factors as $(3x + 2y)(3x - 2y)$.  

c) Rewrite as $x^2y^2 - 1$ as $(xy)^2 - 1^2$. This factors as $(xy + 1)(xy - 1)$.  

**Example 4**

*Factor the difference of squares.*

a) $x^4 - 25$

b) $16x^4 - y^2$

c) $x^2y^8 - 64z^2$

d) $x^2 + 9$

**Solution**

a) Rewrite $x^4 - 25$ as $(x^2)^2 - 5^2$. This factors as $(x^2 + 5)(x^2 - 5)$.  

b) Rewrite $16x^4 - y^2$ as $(4x^2)^2 - y^2$. This factors as $(4x^2 + y)(4x^2 - y)$.  

c) Rewrite $x^2y^4 - 64z^2$ as $(xy^2)^2 - (8z)^2$. This factors as $(xy^2 + 8z)(xy^2 - 8z)$.  

d) $x^2 + 9$ is not a difference of squares. This expression does not factor. We say $x^2 + 9$ is prime.  

**Factor Perfect Square Trinomials**

We use the **Square of a Binomial Formula** to factor perfect square trinomials. A perfect square trinomial has the following form.

$$a^2 + 2ab + b^2 \quad \text{or} \quad a^2 - 2ab + b^2$$

In these special kinds of trinomials, the first and last terms are perfect squares and the middle term is twice the product of the square roots of the first and last terms. In a case like this, the polynomial factors into perfect squares.

$$a^2 + 2ab + b^2 = (a + b)^2$$

$$a^2 - 2ab + b^2 = (a - b)^2$$
In these problems, the key is figuring out what the $a$ and $b$ terms are. Let's do some examples of this type.

**Example 5**

Factor the following perfect square trinomials.

a) $x^2 + 8x + 16$

b) $x^2 - 4x + 4$

c) $x^2 + 14x + 49$

**Solution**

a) $x^2 + 8x + 16$

The first step is to recognize that this expression is actually perfect square trinomials.

1. Check that the first term and the last term are perfect squares. They are indeed because we can rewrite:

   $x^2 + 8x + 16$ as $x^2 + 8x + 4^2$.

2. Check that the middle term is twice the product of the square roots of the first and the last terms. This is true also since we can rewrite them.

   $x^2 + 8x + 16$ as $x^2 + 2 \cdot 4 \cdot x + 4^2$

This means we can factor $x^2 + 8x + 16$ as $(x + 4)^2$.

We can check to see if this is correct by multiplying $(x + 4)(x + 4)$.

   $(x + 4)^2 = (x + 4)(x + 4) = x^2 + 4x + 4x + 16 = x^2 + 8x + 16$

The answer checks out.

We could factor this trinomial without recognizing it as a perfect square. With the methods we learned in the last section we know that a trinomial factors as a product of the two binomials in parentheses.

   $(x \pm ___)(x \pm ___)$

We need to find two numbers that multiply to 16 and add to 8. We can write 16 as the following products.

   $16 = 1 \cdot 16$ and $1 + 16 = 17$

   $16 = 2 \cdot 8$ and $2 + 8 = 10$

   $16 = 4 \cdot 4$ and $4 + 4 = 8$ ← This is the correct choice.

We can factor $x^2 + 8x + 16$ as $(x + 4)(x + 4)$ which is the same as $(x + 4)^2$.

You can always factor by the methods you have learned for factoring trinomials but it is faster if you can recognize special products.

b) Rewrite $x^2 - 4x + 4$ as $x^2 + 2 \cdot (-2) \cdot x + (-2)^2$. 

26
We notice that this is a perfect square trinomial and we can factor it as: \((x - 2)^2\).
c) Rewrite \(x^2 + 14x + 49\) as \(x^2 + 2\cdot 7\cdot x + 7^2\).

We notice that this is a perfect square trinomial as we can factor it as: \((x + 7)^2\).

**Example 6**

*Factor the following perfect square trinomials.*

a) \(4x^2 + 20x + 25\)
b) \(9x^2 - 24x + 16\)
c) \(x^2 + 2xy + y^2\)

**Solution**

a) Rewrite \(4x^2 + 20x + 25\) as \((2x)^2 + 2\cdot 5\cdot (2x) + 5^2\)

We notice that this is a perfect square trinomial and we can factor it as \((2x + 5)^2\).

b) Rewrite \(9x^2 - 24x + 16\) as \((3x)^2 - 2\cdot 4\cdot (3x) + (-4)^2\).

We notice that this is a perfect square trinomial as we can factor it as \((3x - 4)^2\).

We can check to see if this is correct by multiplying \((3x - 4)^2 = (3x - 4)(3x - 4)\).

\[
\begin{array}{c}
3x - 4 \\
3x - 4 \\
-12x + 16 \\
9x^2 - 12x \\
9x^2 - 24x + 16
\end{array}
\]

The product checks out.

c) \(x^2 + 2xy + y^2\)

We notice that this is a perfect square trinomial as we can factor it as \((x + y)^2\).

**Factor a Sum or Difference of Cubes**

We use the **Sum of Difference of Cubes Formula** to factor a sum of difference of cubes. A sum of difference of cubes has one of the following forms.

\[a^3 + b^3 \quad \text{or} \quad a^3 - b^3\]

In these special kinds of binomials, the first and last terms are perfect cubes. In a case like this, the polynomial factors as follows.

\[a^3 + b^3 = (a+b)(a^2 - ab + b^2)\]
\[a^3 - b^3 = (a-b)(a^2 + ab + b^2)\]

In these problems, the key is figuring out what the \(a\) and \(b\) terms are. If you write the binomial in the form \((\phantom{a})^3 \pm (\phantom{a})^3\).

The terms in the parentheses represent \(a\) and \(b\). Lets do some examples of this type.
Example 7
Factor the sum of cubes:

a) \(x^3 - 8\)

b) \(27x^3 + 64y^3\)

Solution

a) \(x^3 - 8 = (x)^3 - (2)^3\) so \(a = x\) and \(b = 2\). The factored form is \((x - 2)(x^2 + 2x + 4)\).

b) Rewrite \(27x^3 + 64y^3\) as \((3x)^3 + (4y)^3\) so \(a = 3x\) and \(b = 4y\). The factored form is \((3x + 4y)(9x^2 - 12xy + 16y^2)\).

Solve Quadratic Polynomial Equations by Factoring

With the methods we learned in the last two sections, we can factor many kinds of quadratic polynomials. This is very helpful when we want to solve quadratic equations such as

\[ax^2 + bx + c = 0\]

Remember that to solve quadratic equations in expanded form we use the following steps:

Step 1
If necessary, rewrite the equation in standard form so that
Polynomial expression = 0.

Step 2
Factor the polynomial completely.

Step 3
Use the Zero-Product rule to set each factor equal to zero.

Step 4
Solve each equation from Step 3.

Step 5
Check your answers by substituting your solutions into the original equation.

We will do a few examples that show how to solve quadratic equations using the factoring methods we just learned.

Example 8
Solve the following quadratic equations.

a) \(x^2 + 7x + 6 = 0\)

b) \(x^2 - 8x = -12\)

c) \(x^2 = 2x + 15\)

Solution

a) \(x^2 + 7x + 6 = 0\)

Technology Note: It is possible to use a graphing calculator to help find the factors of 6 that add to 7. If we enter \(y_1 = 6/x\), the table features will tell us which values of \(x\) are factors of 6. If \(x\) divided evenly into 6, then \(y\) will be an integer.
Now if we view the table we see this.

The table shows the factors of 6.

\[ 6 = 1 \cdot 6 \quad \text{and} \quad 1 + 6 = 7 \quad \leftarrow \quad \text{This is the correct choice.} \]
\[ 6 = 2 \cdot 3 \quad \text{and} \quad 2 + 3 = 5 \]

\[ x^2 + 7x + 6 = 0 \] factors as \((x + 1)(x + 6) = 0\)

Using the algebraic approach like we have been using all along, we follow the steps below.

Rewrite. This is not necessary since the equation is in the correct form already.

Factor. We can write 6 as a product of the following numbers.

\[ 6 = 1 \cdot 6 \quad \text{and} \quad 1 + 6 = 7 \quad \leftarrow \quad \text{This is the correct choice.} \]
\[ 6 = 2 \cdot 3 \quad \text{and} \quad 2 + 3 = 5 \]

\[ x^2 + 7x + 6 = 0 \] factors as \((x + 1)(x + 6) = 0\)

Set each factor equal to zero.

\[ x + 1 = 0 \quad \text{or} \quad x + 6 = 0 \]

Solve.
\[ x = -1 \quad \text{or} \quad x = -6 \]

**Check** Substitute each solution back into the original equation.

\[ x = -1 \quad \text{Checks} \quad (-1)^2 + 7(-1) + 6 = 1 - 7 + 6 = 0 \]
\[ x = -6 \quad \text{Checks} \quad (-6)^2 + 7(-6) + 6 = 36 - 42 + 6 = 0 \]

b) \( x^2 - 8x = -12 \)

**Rewrite** \( x^2 - 8x = -12 \) is rewritten as \( x^2 - 8x + 12 = 0 \).

**Factor.** We can write 12 as a product of the following numbers.

\[
\begin{align*}
12 &= 1 \cdot 12 \quad \text{and} \quad 1 + 12 = 13 \\
12 &= -1 \cdot (-12) \quad \text{and} \quad -1 + (-12) = -13 \\
12 &= 2 \cdot 6 \quad \text{and} \quad 2 + 6 = 8 \\
12 &= -2 \cdot (-6) \quad \text{and} \quad -2 + (-6) = -8 \\
12 &= 3 \cdot 4 \quad \text{and} \quad 3 + 4 = 7 \\
12 &= -3 \cdot (-4) \quad \text{and} \quad -3 + (-4) = -7
\end{align*}
\]

\( x^2 - 8x + 12 = 0 \) factors as \((x - 2)(x - 6) = 0\)

**Set each factor equal to zero.**

\[ x - 2 = 0 \quad \text{or} \quad x - 6 = 0 \]

**Solve.**

\[ x = 2 \quad \text{or} \quad x = 6 \]

**Check.** Substitute each solution back into the original equation.

\[ x = 2 \quad \text{Checks} \quad (2)^2 - 8(2) = 4 - 16 = -12 \]
\[ x = 6 \quad \text{Checks} \quad (6)^2 - 8(6) = 36 - 48 = -12 \]

c) \( x^2 = 2x + 15 \)

**Rewrite** \( x^2 = 2x + 15 \) is re-written as \( x^2 - 2x - 15 = 0 \).

**Factor.** We can write -15 as a product of the following numbers.

\[
\begin{align*}
-15 &= 1 \cdot (-15) \quad \text{and} \quad 1 + (-15) = -14 \\
-15 &= -1 \cdot (15) \quad \text{and} \quad -1 + (15) = 14 \\
-15 &= -3 \cdot 5 \quad \text{and} \quad -3 + 5 = 2 \\
-15 &= 3 \cdot (-5) \quad \text{and} \quad 3 + (-5) = -2
\end{align*}
\]

← This is the correct choice.
\[ x^2 - 2x - 15 = 0 \] factors as \((x + 3)(x - 5) = 0\).

**Set each factor equal to zero**

\[ x + 3 = 0 \quad \text{or} \quad x - 5 = 0 \]

**Solve.**

\[ x = -3 \quad \text{or} \quad x = 5 \]

**Check** Substitute each solution back into the original equation.

\[
\begin{align*}
  x = -3 & \quad (-3)^2 = 2(-3) + 15 \Rightarrow 9 = 0 & \text{Checks} \\
  x = 5 & \quad (5)^2 = 2(5) + 15 \Rightarrow 25 = 25 & \text{Checks.}
\end{align*}
\]

**Example 8**

Solve the following quadratic equations.

a) \[ x^2 - 12x + 36 = 0 \]

b) \[ x^2 - 81 = 0 \]

c) \[ x^2 + 20x + 100 = 0 \]

**Solution**

a) \[ x^2 - 12x + 36 = 0 \]

**Rewrite.** This is not necessary since the equation is in the correct form already.

**Factor.** Re-write \(x^2 - 12x + 36\) as \(x^2 - 2 \cdot (-6)x + (-6)^2\). (We can also use the method for factoring \(x^2 + bx + c\) from the last section and find the factors of \(c\) that add to \(b\).)

We recognize this as a difference of squares. This factors as \((x - 6)^2 = 0\) or \((x - 6)(x - 6) = 0\).

**Set each factor equal to zero.**

\[ x - 6 = 0 \quad \text{or} \quad x - 6 = 0 \]

**Solve.**

\[ x = 6 \quad \text{or} \quad x = 6 \]

Notice that for a perfect square the two solutions are the same. This is called a **double root**.

**Check.** Substitute each solution back into the original equation.

\[
\begin{align*}
  x = 6 & \quad 6^2 - 12(6) + 36 = 36 - 72 + 36 + 0 & \text{Checks} \\
  b) x^2 - 81 = 0
\end{align*}
\]
Rewrite. This is not necessary since the equation is in the correct form already.

Factor Rewrite $x^2 - 81 = 0$ as $x^2 - 9^2 = 0$.

We recognize this as a difference of squares. This factors as $(x - 9)(x + 9) = 0$.

Set each factor equal to zero.

$$x - 9 = 0 \quad \text{or} \quad x + 9 = 0$$

Solve.

$$x = 9 \quad \text{or} \quad x = -9$$

Check. Substitute each solution back into the original equation.

$$x = 9 \quad \text{and} \quad 9^2 - 81 = 81 - 81 = 0 \quad \text{Checks}$$
$$x = -9 \quad \text{and} \quad (-9)^2 - 81 = 81 - 81 = 0 \quad \text{Checks}$$

c) $x^2 + 20x + 100 = 0$

Rewrite. This is not necessary since the equation is in the correct form already.

Factor. Rewrite $x^2 + 20x + 100 = 0$ as $x^2 + 2 \cdot 10 \cdot x + 10^2$

We recognize this as a perfect square trinomial. This factors as: $(x + 10)^2 = 0$ or $(x + 10)(x + 10) = 0$.

Set each factor equal to zero.

$$x + 10 = 0 \quad \text{or} \quad x + 10 = 0$$

Solve.

$$x = -10 \quad \text{or} \quad x = -10 \quad \text{This is a double root.}$$

Check Substitute each solution back into the original equation.

$$x = 10 \quad \text{and} \quad (-10)^2 + 20(-10) + 100 = 100 - 200 + 100 = 0 \quad \text{Checks out.}$$
1.4 Factoring Polynomials Completely and Solving Polynomial Equations by Factoring

Learning Objectives

- Factor out a common binomial.
- Factor by grouping.
- Factor a quadratic trinomial where $a \neq 1$.
- Solve polynomial equations by factoring.
- Solve real world problems using polynomial equations.

Introduction

We say that a polynomial is **factored completely** when we factor as much as we can and we can’t factor any more. Here are some suggestions that you should follow to make sure that you factor completely.

- Factor all common monomials first.
- Identify special products such as difference of squares or the square of a binomial. Factor according to their formulas.
- If there are no special products, factor using the methods we learned in the previous sections.
- Look at each factor and see if any of these can be factored further.

Here are some examples.

**Example 1**

*Factor the following polynomials completely.*

a) $6x^2 - 30x + 36$

b) $2x^2 - 8$

c) $x^3 + 6x^2 + 9x$

**Solution**

a) $6x^2 - 30x + 36$

Factor the common monomial. In this case 6 can be factored from each term.

$$6(x^2 - 5x + 6)$$

There are no special products. We factor $x^2 - 5x + 6$ as a product of two binomials $(x \pm \_)(x \pm \_)$. The two numbers that multiply to 6 and add to -5 are -2 and -3. Let’s substitute them into the two parenthesis. The 6 is outside because it is factored out.

$$6(x^2 - 5x + 6) = 6(x - 2)(x - 3)$$

If we look at each factor we see that we can’t factor anything else.
The factored form is $6(x - 2)(x - 3)$.

b) $2x^2 - 8$

Factor common monomials $2x^2 - 8 = 2(x^2 - 4)$.

We recognize $x^2 - 4$ as a difference of squares. We factor as $2(x^2 - 4) = 2(x + 2)(x - 2)$.

If we look at each factor we see that we can’t factor anything else.

The factored form is $2(x + 2)(x - 2)$.

c) $x^3 + 6x^2 + 9x$

Factor common monomials $x^3 + 6x^2 + 9x = x(x^2 + 6x + 9)$.

We recognize as a perfect square and factor as $x(x + 3)^2$.

If we look at each factor we see that we can’t factor anything else.

The factored form is $x(x + 3)^2$.

Example 2

Factor the following polynomials completely.

a) $-2x^4 + 162$

b) $x^5 - 8x^3 + 16x$

Solution

a) $-2x^4 + 162$

Factor the common monomial. In this case, factor -2 rather than 2. It is always easier to factor when leading coefficient is positive.

$$-2x^4 + 162 = -2(x^4 - 81)$$

We recognize the expression in parenthesis as a difference of squares. We factor and get this result.

$$-2(x^2 - 9)(x^2 + 9)$$

If we look at each factor, we see that the first parenthesis is a difference of squares. After factoring we get:

$$-2(x + 3)(x - 3)(x^2 + 9)$$

If we look at each factor, we see that we can factor no more.

The complete factored form is $-2(x + 3)(x - 3)(x^2 + 9)$.

b) $x^5 - 8x^3 + 16x$

Factor out the common monomial $x^5 - 8x^3 + 16x = x(x^4 - 8x^2 + 16)$.

We recognize $x^4 - 8x^2 + 16$ as a perfect square and we factor it as $x(x^2 - 4)^2$.

We look at each term and recognize that the term in parenthesis is a difference of squares.

We factor and get: $x[(x + 2)(x - 2)]^2 = x[(x + 2)^2(x - 2)^2] = x(x + 2)^2(x - 2)^2$.

We use square brackets [ ] in this expression because x is multiplied by the expression $(x + 2)^2(x - 2)$. When we have nested grouping symbols we use brackets [ and ] to show the levels of nesting.
If we look at each factor now we see that we can’t factor anything else.
The complete factored form is: \(x(x + 2)^2(x - 2)^2\).

**Factor out a Common Binomial**

The first step in the factoring process is often factoring the common monomials from a polynomial. Sometimes polynomials have common terms that are binomials. For example, consider the following expression.

\[x(3x + 2) - 5(3x + 2)\]

You can see that the binomial \((3x + 2)\) appears in both products of the polynomial. This common term can be factored by writing it in front of a parenthesis. Inside the parenthesis, we write all the terms that are left over when we divide them by the common factor.

\[(3x + 2)(x - 5)\]

This expression is now completely factored.

**Example 3**

*Factor the common binomials.*

a) \(3x(x - 1) + 4(x - 1)\)
b) \(x(4x + 5) + (4x + 5)\)

**Solution**

a) \(3x(x - 1) + 4(x - 1)\) has a common binomial of \((x - 1)\).

When we factor the common binomial out, we get \((x - 1)(3x + 4)\).

b) \(x(4x + 5) + (4x + 5)\) has a common binomial of \((4x + 5)\).

When we factor the common binomial out, we get \((4x + 5)(x + 1)\).

**Factor by Grouping**

It may be possible to factor a polynomial containing four or more terms by factoring common monomials from groups of terms. This method is called factor by grouping.

The next example illustrates how this process works.

**Example 4**

*Factor* \(2x + 2y + ax + ay\).

**Solution**

There isn’t a common factor for all four terms in this example. However, there is a factor of 2 that is common to the first two terms and there is a factor of a that is common to the last two terms. Factor 2 from the first two terms and factor \(a\) from the last two terms.

\[2x + 2y + ax + ay = 2(x + y) + a(x + y)\]
Now we notice that the binomial \((x + y)\) is common to both terms. We factor the common binomial and get:

\[(x + y)(2 + a)\]

Our polynomial is now factored completely.

**Example 5**

*Factor \(3x^2 + 6x + 4x + 8\).*

**Solution**

We factor \(3x\) from the first two terms and factor 4 from the last two terms.

\[3x(x + 2) + 4(x + 2)\]

Now factor \((x + 2)\) from both terms.

\[(x + 2)(3x + 4)\]

Now the polynomial is factored completely.

**Factor Quadratic Trinomials Where \(a\)**

Factoring by grouping is a very useful method for factoring quadratic trinomials where \(a \neq 1\). A quadratic polynomial of this type is written in the form:

\[ax^2 + bx + c\]

This does not factor as \((x \pm m)(x \pm n)\), so it is not as simple as looking for two numbers that multiply to give \(c\) and add to give \(b\). In this case, we must take into account the coefficient that appears in the first term.

To factor a quadratic polynomial where \(a \neq 1\), we follow the following steps.

1. We find the product \(ac\).
2. We look for two numbers that multiply to give \(ac\) and add to give \(b\).
3. We rewrite the middle term using the two numbers we just found.
4. We factor the expression by grouping.

**Factor Quadratic Trinomials Where \(a\)**

Trial and error can also be a very useful method for factoring quadratic trinomials where \(a \neq 1\). A quadratic polynomial such as this one.

\[ax^2 + bx + c\]

Using the trial and error process is like undoing the FOIL process used to multiply two binomials. For example the factored form of \(2x^2 - 7x - 15\) is \((2x + 3)(x - 5)\). The the first terms in the binomial factors, \(2x\) and \(x\), are factors of
the first terms of the original trinomial. Also the second terms of the binomial factors, 3 and \(-5\), are factors of the third term or the constant term of the original trinomial. Finally notice the sum of the product of the inner terms and outer terms give the middle term of the original trinomial: \(3x + (-10x) = -7x\). When performing trial and error to factor a quadratic trinomial, the goal is the find the correct factors of \(ax^2\) and \(c\) for the binomial factors.

**Steps to solving a trinomial by trial and error.**

**Step 1** Set up a product of two binomials.

\[
(\quad ) (\quad )
\]

**Step 2** Place the possible factors of \(ax^2\) in the first positions of the binomials.

**Step 3** Place the possible factors of \(c\) in the second positions of the binomial factors.

**Step 4** Keep trying different factors of \(ax^2\) and \(c\) until the sum of the inner product and outer product of the binomials is equal to the middle term, \(bx\), or the original trinomial.

Let’s apply this method to the following examples.

**Example 6**

*Factor the following quadratic trinomials by grouping.*

a) \(3x^2 + 8x + 4\)

b) \(6x^2 - 11x + 4\)

c) \(5x^2 - 6x + 1\)

**Solution**

Let’s follow the steps outlined above.

a) \(3x^2 + 8x + 4\)

**Step 1** \(ac = 3 \cdot 4 = 12\)

**Step 2** The number 12 can be written as a product of two numbers in any of these ways:

\[
\begin{align*}
12 &= 1 \cdot 12 & & \text{and} & \quad 1 + 12 &= 13 \\
12 &= 2 \cdot 6 & & \text{and} & \quad 2 + 6 &= 8 \\
12 &= 3 \cdot 4 & & \text{and} & \quad 3 + 4 &= 7
\end{align*}
\]

**Step 3** Re-write the middle term as: \(8x = 2x + 6x\), so the problem becomes the following.

\[
3x^2 + 8x + 4 = 3x^2 + 2x + 6x + 4
\]

**Step 4**: Factor an \(x\) from the first two terms and 2 from the last two terms.

\[
x(3x + 2) + 2(3x + 2)
\]

Now factor the common binomial \((3x + 2)\).
The factored form is $(3x + 2)(x + 2)$.

To check if this is correct we multiply $(3x + 2)(x + 2)$.

\[(3x + 2)(x + 2) = 3x^2 + 6x + 2x + 4 = 3x^2 + 8x + 4\]

The answer checks out.

b) $6x^2 − 11x + 4$

**Step 1** $ac = 6 \cdot 4 = 24$

**Step 2** The number 24 can be written as a product of two numbers in any of these ways.

\[
\begin{align*}
24 &= 1 \cdot 24 \quad \text{and} \quad 1 + 24 = 25 \\
24 &= -1 \cdot (-24) \quad \text{and} \quad -1 + (-24) = -25 \\
24 &= 2 \cdot 12 \quad \text{and} \quad 2 + 12 = 14 \\
24 &= -2 \cdot (-12) \quad \text{and} \quad -2 + (-12) = -14 \\
24 &= 3 \cdot 8 \quad \text{and} \quad 3 + 8 = 11 \\
24 &= -3 \cdot (-8) \quad \text{and} \quad -3 + (-8) = -11 \leftarrow \text{This is the correct choice.} \\
24 &= 4 \cdot 6 \quad \text{and} \quad 4 + 6 = 10 \\
24 &= -4 \cdot (-6) \quad \text{and} \quad -4 + (-6) = -10
\end{align*}
\]

**Step 3** Re-write the middle term as $-11x = -3x - 8x$, so the problem becomes

\[6x^2 − 11x + 4 = 6x^2 − 3x − 8x + 4\]

**Step 4** Factor by grouping. Factor a $3x$ from the first two terms and factor $-4$ from the last two terms.

\[3x(2x − 1) − 4(2x − 1)\]

Now factor the common binomial $(2x − 1)$.

\[(2x − 1)(3x − 4)\]

Our factored form is $(2x − 1)(3x − 4)$.

c) $5x^2 − 6x + 1$

**Step 1** $ac = 5 \cdot 1 = 5$

**Step 2** The number 5 can be written as a product of two numbers in any of these ways:
5 = 1 \cdot 5 \quad \text{and} \quad 1 + 5 = 6

5 = -1 \cdot (-5) \quad \text{and} \quad -1 + (-5) = -6 \quad \leftarrow \quad \text{This is the correct choice}

**Step 3** Rewrite the middle term as \(-6x = -x - 5x\). The problem becomes

\[5x^2 - 6x + 1 = 5x^2 - x - 5x + 1\]

**Step 4** Factor by grouping. Factor an \(x\) from the first two terms and a factor of -1 from the last two terms:

\[x(5x - 1) - 1(5x - 1)\]

Now factor the common binomial \((5x - 1)\).

\[(5x - 1)(x - 1)\]

Our factored form is \((5x - 1)(x - 1)\).

**Solve Quadratic Equations by Factoring**

Now that we know the basics of factoring, we can solve some simple polynomial equations. We already saw how we can use the Zero-product Property to solve polynomials in factored form. Here you will learn how to solve polynomials in expanded form. These are the steps for this process.

**Step 1**
If necessary, **re-write** the equation in standard form such that:

Polynomial expression = 0.

**Step 2**
**Factor** the polynomial completely.

**Step 3**
Use the zero-product property to set each factor equal to zero.

**Step 4**
Solve each equation from step 3

**Step 5**
Check your answers by substituting your solutions into the original equation.

**Example 7**
*Solve the following polynomial equations.*

a) \(3x^2 - 24x + 36 = 0\)
b) \(2x^2 = 50\)
c) \(12x^2 - 7x - 10 = 0\)
Solution:
a) $3x^2 - 24x + 36 = 0$

**Rewrite.** This is not necessary since the equation is in the correct form.

**Factor out the GCF of the trinomial.** Notice 3 is the greatest common factor.

**Factor** $3(x^2 - 8x + 12) = 0 \Rightarrow 3(x - 6)(x - 2) = 0$

**Set each factor equal to zero.**

$$x - 6 = 0 \quad \text{or} \quad x - 2 = 0$$

**Solve.**

$$x = 6 \quad \text{or} \quad x = 2$$

**Check.** Substitute each solution back into the original equation.

$$x = 6 \quad \Rightarrow \quad 3(6)^2 - 24(6) + 36 = 0 \quad \text{checks}$$
$$x = 2 \quad \Rightarrow \quad 3(2)^2 - 24(2) + 36 = 0 \quad \text{checks}$$

**Answer** $x = 6, x = 2$

b) $2x^2 = 50$

**Rewrite.** $2x^2 - 50 = 0$

**Factor.** $2(x^2 - 25) = 0 \Rightarrow 2(x + 5)(x - 5) = 0.$

**Set each factor equal to zero.**

$$2 \neq 0 \quad \text{or} \quad x - 5 = 0 \quad \text{or} \quad x + 5 = 0$$

**Solve.**

$$x = 5 \quad \text{or} \quad x = -5$$

**Notice the factor of 2 does not contain a variable and does give us a solution. We normally will not set the constant factors equal to zero.**

**Check.** Substitute each solution back into the original equation.

$$x = 5 \Rightarrow 2(5)^2 - 50 = 0 \quad \text{checks}$$
$$x = -5 \Rightarrow 2(-5)^2 - 50 = 0 \quad \text{checks}$$

**Answer** $x = 5, x = -5$
c) \(12x^2 - 7x - 10 = 0\)

**Rewrite.** This step is not needed.

**Factor.**

\[(3x + 2)(4x - 5)\]

Set each factor equal to zero.

\[3x + 2 = 0 \quad \text{or} \quad 4x - 5 = 0\]

**Solve.**

\[x = \frac{-2}{3} \quad \text{or} \quad x = \frac{5}{4}\]

**Check** Substitute each solution back into the original equation.

\[x = -\frac{2}{3} \Rightarrow 12\left(-\frac{2}{3}\right)^2 - 7\left(-\frac{2}{3}\right) - 10 = 0\]
\[x = -\frac{2}{3} \Rightarrow 12\left(\frac{4}{9}\right) - 7\left(-\frac{2}{3}\right) - 10 = 0\]
\[x = -\frac{2}{3} \Rightarrow \left(\frac{48}{9}\right) + \left(\frac{14}{3}\right) - 10 = 0\]
\[x = -\frac{2}{3} \Rightarrow \left(\frac{48}{9}\right) + \left(\frac{42}{9}\right) - 90/9 = 0 \quad \text{checks}\]

\[x = \frac{5}{4} \Rightarrow 12\left(\frac{5}{4}\right)^2 - 7\left(\frac{5}{4}\right) - 10 = 0\]
\[x = \frac{5}{4} \Rightarrow 12\left(\frac{25}{16}\right) - 7\left(\frac{5}{4}\right) - 10 = 0\]
\[x = \frac{5}{4} \Rightarrow \left(\frac{300}{16}\right) - \left(\frac{35}{4}\right) - 10 = 0\]
\[x = \frac{5}{4} \Rightarrow \left(\frac{300}{16}\right) - \left(\frac{140}{16}\right) - \left(\frac{160}{16}\right) = 0 \quad \text{checks}\]

**Answer** \(x = -\frac{2}{3}, x = \frac{5}{4}\)

**Solve Real-World Problems Using Polynomial Equations**

Now that we know most of the factoring strategies for quadratic polynomials we can see how these methods apply to solving real world problems.

**Example 8 Pythagorean Theorem**

*One leg of a right triangle is 3 feet longer than the other leg. The hypotenuse is 15 feet. Find the dimensions of the right triangle.*

**Solution**
Let \( x \) = the length of one leg of the triangle, then the other leg will measure \( x + 3 \).

Let’s draw a diagram.

Use the Pythagorean Theorem \( (\text{leg}_1)^2 + (\text{leg}_2)^2 = (\text{hypotenuse})^2 \) or \( a^2 + b^2 = c^2 \).

Here \( a \) and \( b \) are the lengths of the legs and \( c \) is the length of the hypotenuse.

Let’s substitute the values from the diagram.

\[
a^2 + b^2 = c^2
\]
\[
x^2 + (x + 3)^2 = 15^2
\]

In order to solve, we need to get the polynomial in standard form. We must first distribute, collect like terms and re-write in the form polynomial \( = 0 \).

\[
x^2 + (x + 3)^2 = 15^2
\]
\[
x^2 + x^2 + 6x + 9 = 225
\]
\[
2x^2 + 6x + 9 = 225
\]
\[
2x^2 + 6x - 216 = 0
\]

**Factor** the common monomial \( 2(x^2 + 3x - 108) = 0 \).

To factor the trinomial inside the parenthesis we need to two numbers that multiply to -108 and add to 3. It would take a long time to go through all the options so let’s try some of the bigger factors.

\[
-108 = -12 \cdot 9 \quad \text{and} \quad -12 + 9 = -3
\]
\[
-108 = 12 \cdot (-9) \quad \text{and} \quad 12 + (-9) = 3 \quad \leftarrow \quad \text{This is the correct choice.}
\]

We factor as: \( 2(x - 9)(x + 12) = 0 \).

**Set each term equal to zero and solve.**

\[
x - 9 = 0 \quad \text{or} \quad x + 12 = 0
\]
\[
x = 9 \quad \text{or} \quad x = -12
\]
It makes no sense to have a negative answer for the length of a side of the triangle, so the answer must be the following.

**Answer** $x = 9$ and $x + 3 = 12$, so one leg is 9 feet and the other leg is 12 feet.

**Check** $9^2 + 12^2 = 81 + 144 = 225 = 15^2$ so the answer checks.

**Example 9 Number Problems**
*The product of two positive numbers is 60. Find the two numbers if one of the numbers is 4 more than the other.*

**Solution**
Let $x =$ one of the numbers and $x + 4 =$ equals the other number.

The product of these two numbers equals 60. We can write the equation.

$$x(x + 4) = 60$$

In order to solve we must write the polynomial in standard form. Distribute, collect like terms and re-write in the form polynomial $= 0$.

$$x^2 + 4x = 60$$

$$x^2 + 4x - 60 = 0$$

**Factor** by finding two numbers that multiply to -60 and add to 4. List some numbers that multiply to -60:

- $-60 = -4 \cdot 15$ and $-4 + 15 = 11$
- $-60 = 4 \cdot (-15)$ and $4 + (-15) = -11$
- $-60 = -5 \cdot 12$ and $-5 + 12 = 7$
- $-60 = 5 \cdot (-12)$ and $5 + (-12) = -7$
- $-60 = -6 \cdot 10$ and $-6 + 10 = 4$ ← This is the correct choice.
- $-60 = 6 \cdot (-10)$ and $6 + (-10) = -4$

The expression factors as $(x + 10)(x - 6) = 0$.

**Set each term equal to zero and solve.**

$$x + 10 = 0$$

$$x = -10$$

or

$$x - 6 = 0$$

$$x = 6$$

Since we are looking for positive numbers, the answer must be the following.

**Answer** $x = 6$ and $x + 4 = 10$, so the two numbers are 6 and 10.

**Check** $6 \cdot 10 = 60$ so the answer checks.

**Example 10 Area of a rectangle**
*A rectangle has sides of $x + 5$ and $x - 3$. What value of $x$ gives and area of 48?*
Area of the rectangle = length × width
Make a sketch of this situation.

\[(x + 5)(x - 3) = 48\]

In order to solve, we must write the polynomial in standard form. Distribute, collect like terms and rewrite in the form polynomial = 0.

\[x^2 + 2x - 15 = 48\]
\[x^2 + 2x - 63 = 0\]

**Factor** by finding two numbers that multiply to -63 and add to 2. List some numbers that multiply to -63.

\[-63 = 7 \cdot (-9) \quad \text{and} \quad 7 + (-9) = -2\]
\[-63 = -7 \cdot 9 \quad \text{and} \quad -7 + 9 = 2 \quad \leftarrow \quad \text{This is the correct choice.}\]

The expression factors as \((x + 9)(x - 7) = 0\).

**Set each term equal to zero and solve.**

\[x + 9 = 0 \quad \text{or} \quad x - 7 = 0\]
\[x = -9 \quad \text{or} \quad x = 7\]

Since we are looking for positive numbers, the answer must be \(x = 7\).

**Answer** The width is \(x - 3 = 4\) and \(x + 5 = 12\), so the width is 4 and the length is 7.

**Check** \(4 \cdot 12 = 48\) so the answer checks out.

2.1 Variation Models

Learning Objectives

- Distinguish direct and inverse variation.
- Graph inverse variation equations.
- Write inverse variation equations.
- Solve real-world problems using inverse variation equations.

Introduction

Many variables in real-world problems are related to each other by variations. A variation is an equation that relates a variable to one or more variables by the operations of multiplication and division. There are three different kinds of variation problems: **direct variation**, **inverse variation** and **joint variation**.

Distinguish Direct and Inverse Variation

In direct variation relationships, the related variables will either increase together or decrease together at a steady rate. For instance, consider a person walking at a constant rate of three miles per hour. As time increases, the distance covered by the person walking also increases at the rate of three miles each hour. The distance and time are related to each other by a direct variation.

\[
\text{distance} = \text{rate} \times \text{time}
\]

Since the speed is a constant 3 miles per hour, we can write: \( d = 3t \).

**Direct Variation**

The general equation for a direct variation is of the form

\[
y = kx.
\]

\( k \) is called the **constant of proportionality**

You can see from the equation that a direct variation is a linear equation with a \( y \)-intercept of zero. The graph of a direct variation relationship is a straight line passing through the origin whose slope is \( k \) the constant of proportionality.
A second type of variation is inverse variation. When two quantities are related to each other inversely, as one quantity increases, the other one decreases and vice-versa in a way that the product of the two quantities remains constant.

For instance, if we look at the formula distance = rate × time again and solve for time, we obtain:

$$time = \frac{distance}{rate}$$

If we keep the distance constant, we see that as the speed of an object increases, then the time it takes to cover that distance decreases. Consider a car traveling a distance of 90 miles, then the formula relating time and speed is $t = \frac{90}{r}$.

**Inverse Variation**

The general equation for inverse variation is of the form

$$y = \frac{k}{x}$$

where $k$ is called the **constant of proportionality**.

In this chapter, we will investigate how the graph of these relationships behave.

Another type variation is a **joint variation**. In this type of relationship, one variable may vary as a product of two or more variables.

For example, the volume of a cylinder is given by:

$$V = \pi r^2 \cdot h$$

In this formula, the volume varies directly as the product of the square of the radius of the base and the height of the cylinder. The constant of proportionality here is the number $\pi$.

In many application problems, the relationship between the variables is a combination of variations. For instance Newton’s Law of Gravitation states that the force of attraction between two spherical bodies varies jointly as the masses of the objects and inversely as the square of the distance between them:

$$F = G \frac{m_1 m_2}{d^2}$$
In this example the constant of proportionality, $G$, is called the gravitational constant and its value is given by $G \approx 6.674 \times 10^{-11} N \cdot m^2/kg^2$.

**Graph Inverse Variation Equations**

We saw that the general equation for inverse variation is given by the formula $y = \frac{k}{x}$, where $k$ is a constant of proportionality. We will now show how the graphs of such relationships behave. We start by making a table of values. In most applications, $x$ and $y$ are positive. So in our table, we will choose only positive values of $x$.

**Example 1**

*Graph an inverse variation relationship with the proportionality constant $k = 1$.*

**Solution**

Since $k = 1$, the inverse variation is given by the equation $y = \frac{1}{x}$.

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$y = \frac{1}{0}$ is undefined</td>
</tr>
<tr>
<td>$\frac{1}{4}$</td>
<td>$y = \frac{1}{\frac{1}{4}} = 4$</td>
</tr>
<tr>
<td>$\frac{1}{2}$</td>
<td>$y = \frac{1}{\frac{1}{2}} = 2$</td>
</tr>
<tr>
<td>$\frac{1}{4}$</td>
<td>$y = \frac{1}{\frac{1}{4}} \approx 1.33$</td>
</tr>
<tr>
<td>1</td>
<td>$y = \frac{1}{1} = 1$</td>
</tr>
<tr>
<td>$\frac{3}{2}$</td>
<td>$y = \frac{1}{\frac{3}{2}} \approx 0.67$</td>
</tr>
<tr>
<td>2</td>
<td>$y = \frac{1}{2} = 0.5$</td>
</tr>
<tr>
<td>3</td>
<td>$y = \frac{1}{3} \approx 0.33$</td>
</tr>
<tr>
<td>4</td>
<td>$y = \frac{1}{4} = 0.25$</td>
</tr>
<tr>
<td>5</td>
<td>$y = \frac{1}{5} = 0.2$</td>
</tr>
<tr>
<td>10</td>
<td>$y = \frac{1}{10} = 0.1$</td>
</tr>
</tbody>
</table>

Here is a graph showing these points connected with a smooth curve.

Both the table and the graph demonstrate the relationship between variables in an inverse variation. As one variable increases, the other variable decreases and vice-versa. Notice that when $x = 0$, the value of $y$ is undefined. The graph shows that when the value of $x$ is very small, the value of $y$ is very big and it approaches infinity as $x$ gets closer and closer to zero.
Similarly, as the value of \( x \) gets very large, the value of \( y \) gets smaller and smaller, but never reaches the value of zero. We will investigate this behavior in detail throughout this chapter.

**Write Inverse Variation Equations**

As we saw earlier, an inverse variation fulfills the equation: \( y = \frac{k}{x} \). In general, we need to know the value of \( y \) at a particular value of \( x \) in order to find the proportionality constant. After the proportionality constant is known, we can find the value of \( y \) for any given value of \( x \).

**Example 2**

\( y \) is inversely proportional to \( x \), and \( y = 10 \) when \( x = 5 \). Find \( y \) when \( x = 2 \).

**Solution**

Since \( y \) is inversely proportional to \( x \),

then the general relationship tells us:

\[ y = \frac{k}{x} \]

Substitute in the values \( y = 10 \) and \( x = 5 \).

\[ 10 = \frac{k}{5} \]

Solve for \( k \) by multiplying both sides of the equation by 5.

\[ k = 50 \]

Now we put \( k \) back into the general equation.

The inverse relationship is given by:

\[ y = \frac{50}{x} \]

When \( x = 2 \) :

\[ y = \frac{50}{2} \text{ or } y = 25 \]

**Answer** \( y = 25 \)

**Example 3**

If \( p \) is inversely proportional to the square of \( q \), and \( p = 64 \) when \( q = 3 \). Find \( p \) when \( q = 5 \).

**Solution:**

Since \( p \) is inversely proportional to \( q^2 \),

then the general equation is:

\[ p = \frac{k}{q^2} \]

Substitute in the values \( p = 64 \) and \( q = 3 \).

\[ 64 = \frac{k}{3^2} \text{ or } 64 = \frac{k}{9} \]

Solve for \( k \) by multiplying both sides of the equation by 9.

\[ k = 576 \]

The inverse relationship is given by:

\[ p = \frac{576}{q^2} \]

When \( q = 5 \) :

\[ p = \frac{576}{25} \text{ or } p = 23.04 \]

**Answer** \( p = 23.04 \).

**Solve Real-World Problems Using Inverse Variation Equations**

Many formulas in physics are described by variations. In this section we will investigate some problems that are described by inverse variations.
2.1. Variation Models

Example 4

The frequency, \( f \), of sound varies inversely with wavelength, \( \lambda \). A sound signal that has a wavelength of 34 meters has a frequency of 10 hertz. What frequency does a sound signal of 120 meters have?

Solution

The inverse variation relationship is

\[ f = \frac{k}{\lambda} \]

Substitute in the values \( \lambda = 34 \) and \( f = 10 \).

\[ 10 = \frac{k}{34} \]

Multiply both sides by 34.

\[ k = 340 \]

Thus, the relationship is given by:

\[ f = \frac{340}{\lambda} \]

Plug in \( \lambda = 120 \) meters.

\[ f = \frac{340}{120} \Rightarrow f \approx 2.83 \]

Answer \( f = 2.83 \) Hertz

Example 5

Electrostatic force is the force of attraction or repulsion between two charges. The electrostatic force is given by the formula:

\[ F = \left(\frac{Kq_1q_2}{d^2}\right) \]

where \( q_1 \) and \( q_2 \) are the charges of the charged particles, \( d \) is the distance between the charges and \( k \) is proportionality constant. In this example, the charges \( q_1 \) and \( q_2 \) do not change and are, thus, constants and can then be combined with the other constant \( k \) to form a new constant \( K \). The equation is rewritten as \( F = \left(\frac{K}{d^2}\right) \).

If the electrostatic force is 740 Newtons when the distance between charges is \( 5.3 \times 10^{-11} \) meters, what is \( F \) when \( d = 2.0 \times 10^{-10} \) meters?

Solution

The inverse variation relationship is

\[ F = \frac{K}{d^2} \]

Plug in the values \( F = 740 \) and \( d = 5.3 \times 10^{-11} \).

Multiply both sides by \( (5.3 \times 10^{-11})^2 \).

The electrostatic force is given by

When \( d = 2.0 \times 10^{-10} \)

Enter \( \frac{2.08 \times 10^{-18}}{(2.0 \times 10^{-10})^2} \) into a calculator.

\[ 740 = \frac{K}{(5.3 \times 10^{-11})^2} \]

\[ K = 740 (5.3 \times 10^{-11})^2 \approx 2.08 \times 10^{-18} \]

\[ F = \frac{2.08 \times 10^{-18}}{d^2} \]

\[ F = \frac{2.08 \times 10^{-18}}{(2.0 \times 10^{-10})^2} \]

\[ F = 52 \]

Answer \( F = 52 \) Newtons

Note: In the last example, you can also compute \( F = \frac{2.08 \times 10^{-18}}{(2.0 \times 10^{-10})^2} \) by hand.
\[ F = \frac{2.08 \times 10^{-18}}{(2.0 \times 10^{-10})^2} \]
\[ = \frac{2.08 \times 10^{-18}}{4.0 \times 10^{-20}} \]
\[ = \frac{2.08 \times 10^{20}}{4.0 \times 10^{18}} \]
\[ = \frac{2.08}{4.0} \left( 10^2 \right) \]
\[ = 0.52(100) \]
\[ = 52 \]

This illustrates the usefulness of scientific notation.
Learning Objectives

- Compare graphs of inverse variation equations.
- Graph rational functions.
- Solve real-world problems using rational functions.

Introduction

In this section, you will learn how to graph rational functions. Graphs of rational functions are very distinctive. These functions are characterized by the fact that the function gets closer and closer to certain values but never reaches those values. In addition, because rational functions may contain values of \( x \) where the function does not exist, the function can take values very close to the excluded values but never cross through these values. This behavior is called asymptotic behavior and we will see that rational functions can have **horizontal asymptotes**, **vertical asymptotes** or **oblique (or slant) asymptotes**.

Compare Graphs of Inverse Variation Equations

Inverse variation problems are the simplest example of rational functions. We saw that an inverse variation has the general equation: \( y = \frac{k}{x} \) or \( f(x) = \frac{k}{x} \). In most real-world problems, the \( x \) and \( y \) values take only positive values. Below, we will show graphs of three inverse variation functions.

Example 1

*On the same coordinate grid, graph an inverse variation relationships with the proportionality constants \( k = 1, k = 2, \) and \( k = \frac{1}{2} \).*

Solution

We will not show the table of values for this problem, but rather we can show the graphs of the three functions on the same coordinate axes. We notice that for larger constants of proportionality, the curve decreases at a slower rate than for smaller constants of proportionality. This makes sense because, basically the value of \( y \) is a result of dividing the proportionality constant by the input value \( x \), so we should expect larger values of \( y \) for larger values of \( k \).
Graph Rational Functions

We will now extend the domain and range of rational equations to include negative values of $x$ and $y$. We will first plot a few rational functions by using a table of values, and then we will talk about distinguishing characteristics of rational functions that will help us make better graphs.

Recall that one of the basic rules of arithmetic is that although 0 can be divided by a nonzero number, you cannot divide a number by 0. So:

$$\frac{0}{5} = 0$$

while

$$\frac{5}{0} \text{ is Undefined.}$$

Recall in arithmetic, we used the relationship between multiplication and division to justify why these facts are true: If $\frac{a}{b} = c$, then $b \times c = a$ and vice versa. There is no number, which when multiplied by 0, gives 5. So there is no number for which $\frac{5}{0}$ is defined.

As we graph rational functions, we need to always pay attention to values of $x$ that will cause us to divide by 0.

**Example 2**

*Graph the function $f(x) = \frac{1}{x}$.*

**Solution**

Before we make a table of values, we should notice that the function is not defined for $x = 0$. This means that the graph of the function will not have a value at that point. Since the value of $x = 0$ is special, we should make sure to pick enough values close to $x = 0$ in order to get a good idea how the graph behaves. Let’s make two tables: one for $x$—values smaller than zero and one for $x$—values larger than zero. For the table of values it may be helpful to replace $f(x)$ with $y$. Let $y = \frac{1}{x}$, where $y = f(x)$.

**Table 2.2:**

<table>

<td>( y = \frac{1}{0.1} = 10 )</td>
</tr>
<tr>
<td>0.2</td>
<td>( y = \frac{1}{0.2} = 5 )</td>
</tr>
<tr>
<td>0.3</td>
<td>( y = \frac{1}{0.3} \approx 3.3 )</td>
</tr>
<tr>
<td>0.4</td>
<td>( y = \frac{1}{0.4} = 2.5 )</td>
</tr>
<tr>
<td>0.5</td>
<td>( y = \frac{1}{0.5} = 2 )</td>
</tr>
<tr>
<td>1</td>
<td>( y = \frac{1}{1} = 1 )</td>
</tr>
<tr>
<td>2</td>
<td>( y = \frac{1}{2} = 0.5 )</td>
</tr>
<tr>
<td>3</td>
<td>( y = \frac{1}{3} \approx 0.33 )</td>
</tr>
<tr>
<td>4</td>
<td>( y = \frac{1}{4} = 0.25 )</td>
</tr>
<tr>
<td>5</td>
<td>( y = \frac{1}{5} = 0.2 )</td>
</tr>
</tbody>
</table>

We can see in the table that as we pick positive values of \( x \) closer and closer to zero, \( y \) becomes increasing large. As we pick negative values of \( x \) closer and close to zero, \( y \) becomes increasingly small (or more and more negative).

Notice on the graph that for values of \( x \) near 0, the points on the graph get closer and closer to the vertical line \( x = 0 \). The line \( x = 0 \) is called a **vertical asymptote** of the function \( f(x) = \frac{1}{x} \).

We also notice that as \( x \) gets larger in the positive direction or in the negative direction, the value of \( y \) gets closer and closer to, but it will never actually equal zero. Why? Since \( f(x) = \frac{1}{x} \), there are no values of \( x \) that will make the fraction zero. For a fraction to equal zero, the numerator must equal zero. The horizontal line \( y = 0 \) is called a **horizontal asymptote** of the function \( f(x) = \frac{1}{x} \).

Asymptotes are usually denoted as dashed lines on a graph. They are not part of the function. A vertical asymptote shows that the function cannot take the value of \( x \) represented by the asymptote. A horizontal asymptote shows the value of \( y \) that the function approaches for large absolute values of \( x \).
Here we show the graph of our function with the vertical and horizontal asymptotes drawn on the graph.
Next we will show the graph of a rational function that has a vertical asymptote at a non-zero value of $x$.

**Example 3**

*Graph the function $f(x) = \frac{1}{(x-2)^2}$.***

**Solution**

Before we make a table of values we can see that the function is not defined for $x = 2$ because that will cause division by 0. This tells us that there should be a vertical asymptote at $x = 2$. We start graphing the function by drawing the vertical asymptote.

Now let's make a table of values. Let $y = \frac{1}{(x-2)^2}$, where $y = f(x)$.

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$y = \frac{1}{(0-2)^2} = \frac{1}{4}$</td>
</tr>
<tr>
<td>1</td>
<td>$y = \frac{1}{(1-2)^2} = 1$</td>
</tr>
<tr>
<td>1.5</td>
<td>$y = \frac{1}{(1.5-2)^2} = 4$</td>
</tr>
<tr>
<td>2</td>
<td>undefined</td>
</tr>
<tr>
<td>2.5</td>
<td>$y = \frac{1}{(2.5-2)^2} = 4$</td>
</tr>
<tr>
<td>3</td>
<td>$y = \frac{1}{(3-2)^2} = 1$</td>
</tr>
<tr>
<td>4</td>
<td>$y = \frac{1}{(4-2)^2} = \frac{1}{4}$</td>
</tr>
</tbody>
</table>

Here is the resulting graph.
Notice that we did not pick as many values for our table this time. This is because we should have a good idea what happens near the vertical asymptote. We also know that for large values of \( x \), both positive and negative, the value of \( y \) could approach a constant value.

In this case, that constant value is \( y = 0 \). This is the horizontal asymptote.

A rational function does not need to have a vertical or horizontal asymptote. The next example shows a rational function with no vertical asymptotes.

**Example 4**

Graph the function \( f(x) = \frac{x^2}{x^2+1} \).

**Solution**

We can see that this function will have no vertical asymptotes because the denominator of the function will never be zero. Let's make a table of values to see if the value of \( y \) approaches a particular value for large values of \( x \), both positive and negative.

Let \( y = \frac{x^2}{x^2+1} \), where \( y = f(x) \).

**Table 2.5:**

<table>
<thead>
<tr>
<th>( x )</th>
<th>( y = \frac{x^2}{x^2+1} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>( \frac{(-3)^2}{(-3)^2+1} = \frac{9}{10} = 0.9 )</td>
</tr>
<tr>
<td>-2</td>
<td>( \frac{(-2)^2}{(-2)^2+1} = \frac{4}{5} = 0.8 )</td>
</tr>
<tr>
<td>-1</td>
<td>( \frac{(-1)^2}{(-1)^2+1} = \frac{1}{2} = 0.5 )</td>
</tr>
<tr>
<td>0</td>
<td>( \frac{0^2}{0^2+1} = \frac{0}{1} = 0 )</td>
</tr>
<tr>
<td>1</td>
<td>( \frac{1^2}{1^2+1} = \frac{1}{2} = 0.5 )</td>
</tr>
<tr>
<td>2</td>
<td>( \frac{2^2}{2^2+1} = \frac{4}{5} = 0.8 )</td>
</tr>
<tr>
<td>3</td>
<td>( \frac{3^2}{3^2+1} = \frac{9}{10} = 0.9 )</td>
</tr>
</tbody>
</table>

Below is the graph of this function.

The function has no vertical asymptote. However, we can see that as the values of \( |x| \) get larger, the value of \( y \) get closer and closer to 1, so the function has a horizontal asymptote at \( y = 1 \).

**Holes in Graphs of Rational Functions**

When a value of \( x \) makes both the numerator and denominator equal to zero, there is a hole in the graph at that value of \( x \). This means at a single point for which the numerator and denominator equals zero, there is a hole in
the graph, not a vertical asymptote. The numerator and denominator are both equal to zero when the numerator and
 denominator share a common factor containing a variable.

If we consider the rational function:

$$f(x) = \frac{x^2 - 2x - 3}{x^2 - 5x + 6}$$

Factor the numerator and denominator.

$$f(x) = \frac{(x-3)(x+1)}{(x-3)(x-2)}$$

Notice $x = 3$ and $x = 2$ make the denominator equal to zero. However, $x = 3$ makes the numerator and denominator
equal to zero. As a result, the graph has a hole at $x = 3$ and a vertical asymptote at $x = 2$. See the graph of $f(x)$
below.

Notice if we simplify the function:

$$f(x) = \frac{(x-3)^1(x+1)}{(x-3)^1(x-2)} = \frac{x+1}{x-2}$$

The graph above looks just like the graph of $f(x) = \frac{x+1}{x-2}$ except for the hole at $x = 2$.

We need to remember that values of $x$ that only make the denominator equal zero will result in vertical asymptotes. However, values of $x$ that make both the numerator and denominator equal to zero will result in a hole in the graph.
2.2. Graphs of Rational Functions

More on Horizontal Asymptotes

We said that a horizontal asymptote is the value of $y$ that the function approaches for large values of $|x|$. When we plug in large values of $x$ in our function, higher powers of $x$ get larger more quickly than lower powers of $x$. For example,

$$f(x) = \frac{2x^2 + x - 1}{3x^2 - 4x + 3}$$

If we plug in a large value of $x$, say $x = 100$, we obtain:

$$y = \frac{2(100)^2 + (100) - 1}{3(100)^2 - 4(100) + 3} = \frac{20000 + 100 - 1}{30000 - 400 + 2}$$

We can see that the first terms in the numerator and denominator are much bigger that the other terms in each expression. One way to find the horizontal asymptote of a rational function is to ignore all terms in the numerator and denominator except for the highest powers.

In this example the horizontal asymptote is $y = \frac{2x^2}{3x^2}$ which simplifies to $y = \frac{2}{3}$.

In the function above, the highest power of $x$ was the same in the numerator as in the denominator. Now consider a function where the power in the numerator is less than the power in the denominator.

$$f(x) = \frac{x}{x^2 + 3}$$

As before, we ignore all but the terms except the highest power of $x$ in the numerator and the denominator.

The horizontal asymptote is $y = \frac{x}{x^2}$ which simplifies to $y = \frac{1}{x}$.

For large values of $x$, the value of $y$ gets closer and closer to zero. Therefore the horizontal asymptote in this case is $y = 0$.

To Summarize:

- Find vertical asymptotes by setting the denominator equal to zero and solving for $x$.
- For horizontal asymptotes, we must consider several cases for finding horizontal asymptotes.
  - If the highest power of $x$ in the numerator is less than the highest power of $x$ in the denominator, then the horizontal asymptote is at $y = 0$.
  - If the highest power of $x$ in the numerator is the same as the highest power of $x$ in the denominator, then the horizontal asymptote is at $y = \frac{\text{coefficient of highest power of } x}{\text{coefficient of highest power of } x}$.
  - If the highest power of $x$ in the numerator is greater than the highest power of $x$ in the denominator, then we don’t have a horizontal asymptote, we could have what is called an oblique (slant) asymptote or no asymptote at all.

Example 5

Find the vertical and horizontal asymptotes for the following functions.

a) $f(x) = \frac{1}{x-1}$

b) $f(x) = \frac{3x}{4x+2}$

c) $f(x) = \frac{x^2-2}{2x^3+3}$
d) \( f(x) = \frac{x^3}{x^2 - 3x + 2} \)

Solution

a) Vertical asymptotes
Set the denominator equal to zero. \( x - 1 = 0 \Rightarrow x = 1 \) is the vertical asymptote.

b) Horizontal asymptote
Keep only highest powers of \( x \). \( y = \frac{1}{x} \Rightarrow y = 0 \) is the horizontal asymptote.

c) Vertical asymptotes
Set the denominator equal to zero. \( 4x + 2 = 0 \Rightarrow x = -\frac{1}{2} \) is the vertical asymptote.

b) Horizontal asymptote
Keep only highest powers of \( x \). \( y = \frac{3}{4x} \Rightarrow y = \frac{3}{4} \) is the horizontal asymptote.

c) Vertical asymptotes
Set the denominator equal to zero. \( 2x^2 + 3 = 0 \Rightarrow 2x^2 = -3 \Rightarrow x^2 = -\frac{3}{2} \) Since there are no solutions to this equation there is no vertical asymptote.

b) Horizontal asymptote
Keep only highest powers of \( x \). \( y = \frac{x^2}{2x} \Rightarrow y = \frac{1}{2} \) is the horizontal asymptote.

d) Vertical asymptotes
Set the denominator equal to zero. \( x^2 - 3x + 2 = 0 \)
Factor. \((x - 2)(x - 1) = 0\)
Solve. \( x = 2 \) and \( x = 1 \) are vertical asymptotes.

Horizontal asymptote. There is no horizontal asymptote because power of numerator is larger than the power of the denominator

Notice the function in part d of Example 5 had more than one vertical asymptote. Here is an example of another function with two vertical asymptotes.

Example 6

Graph the function \( f(x) = \frac{-x^2}{x^2 - 4} \).

Solution

We start by finding where the function is undefined.
Lets set the denominator equal to zero. \( x^2 - 4 = 0 \)
Factor. \((x - 2)(x + 2) = 0\)
Solve. \( x = 2 \) and \( x = -2 \)

We find that the function is undefined for \( x = 2 \) and \( x = -2 \), so we know that there are vertical asymptotes at these values of \( x \).

We can also find the horizontal asymptote by the method we outlined above.

Horizontal asymptote is at \( y = \frac{-x^2}{x^2} = -1 \) or \( y = -1 \).

Start plotting the function by drawing the vertical and horizontal asymptotes on the graph.

Now, lets make a table of values. Because our function has a lot of detail we must make sure that we pick enough values for our table to determine the behavior of the function accurately. We must make sure especially that we pick values close to the vertical asymptotes.
Let \( y = \frac{-x^2}{x^2 - 4} \), where \( y = f(x) \)

### Table 2.6:

<table>
<thead>
<tr>
<th>( x )</th>
<th>( y )</th>

### Solve Real-World Problems Using Rational Functions

#### Electrical Circuits

Electrical circuits are commonplace in everyday life. For instance, they are present in all electrical appliances in your home. The figure below shows an example of a simple electrical circuit. It consists of a battery which provides a voltage \( V \), measured in Volts \( V \), a resistor \( R \), measured in ohms \( \Omega \) which resists the flow of electricity, and an ammeter that measures the current \( I \), measured in amperes \( A \) in the circuit.
Ohm’s Law gives a relationship between current, voltage and resistance. It states that

\[ I = \frac{V}{R} \]

Your light bulb, toaster and hairdryer are all basically simple resistors. In addition, resistors are used in an electrical circuit to control the amount of current flowing through a circuit and to regulate voltage levels. One important reason to do this is to prevent sensitive electrical components from burning out due to too much current or too high a voltage level. Resistors can be arranged in series or in parallel.

For resistors placed in a series, the total resistance is just the sum of the resistances of the individual resistors.

\[ R_{tot} = R_1 + R_2 \]

For resistors placed in parallel, the reciprocal of the total resistance is the sum of the reciprocals of the resistance of the individual resistors.

\[ \frac{1}{R_{tot}} = \frac{1}{R_1} + \frac{1}{R_2} \]

Example 7

Find the quantity labeled x in the following circuit.
Solution

We use the formula that relates voltage, current and resistance $I = \frac{V}{R}$.

Substitute in the known values: $I = 2, V = 12$: $2 = \frac{12}{R}$

Multiply both sides by $R$. $2R = 12$

Divide both sides by 2. $R = 6 \text{ } \Omega$

**Answer** $6 \text{ } \Omega$

**Example 8**

*Find the quantity labeled $x$ in the following circuit.*

![Circuit Diagram]

**Solution**

Ohms Law also says $I_{total} = \frac{V_{total}}{R_{total}}$.

Plug in the values we know, $I = 2.5$ and $V = 9$.

$2.5 = \frac{9}{R_{total}}$

Multiply both sides by $R_{total}$: $2.5R_{total} = 9$

Divide both sides by 2.5. $R_{total} = 3.6 \text{ } \Omega$

Since the resistors are placed in parallel, the total resistance is given by

$$\frac{1}{R_{total}} = \frac{1}{x} + \frac{1}{20}$$

Subtract $\frac{1}{20}$ on both sides: $\frac{1}{3.6} - \frac{1}{20} = \frac{1}{x}$

Build up fraction on the left to find a common denominator: $\frac{20}{72} - \frac{3.6}{72} = \frac{1}{x}$

Subtract the fractions: $\frac{16.4}{72} = \frac{1}{x}$

Use proportions and solve: $16.4x = 72$

Divide both sides by 6.4: $x = 4.39 \text{ } \Omega$

**Answer** $x = 4.39 \text{ } \Omega$
## 2.3 Rational Expressions

### Learning Objectives

- Simplify rational expressions.
- Find excluded values of rational expressions.
- Simplify rational models of real-world situations.

### Introduction

A rational expression is reduced to lowest terms by factoring the numerator and denominator completely and divide out common factors. For example, the expression

\[
\frac{x \cdot z^1}{y \cdot z^1} = \frac{x}{y}
\]

simplifies to simplest form by dividing out the common factor \( z \).

### Simplify Rational Expressions.

To simplify rational expressions means that the numerator and denominator of the rational expression have no common factors. In order to simplify to lowest terms, we factor the numerator and denominator as much as we can and divide out common factors from the numerator and the denominator of the fraction.

**Example 1**

Simplify each rational expression.

a) \( \frac{4x-2}{2x^2+x-1} \)

b) \( \frac{x^2-2x+1}{8x-8} \)

c) \( \frac{x^2-4}{x^2-5x+6} \)

**Solution**

a) Factor the numerator and denominator completely. \( \frac{2(2x-1)}{(2x-1)(x+1)} \)

Divide the common term \((2x-1)\). **Answer** \( \frac{2}{x+1} \)

b) Factor the numerator and denominator completely. \( \frac{(x-1)(x-1)}{8(x-1)} \)

Divide the common term \((x-1)\). **Answer** \( \frac{1}{8} \)

c) Factor the numerator and denominator completely. \( \frac{(x-2)(x+2)}{(x-2)(x-3)} \)

Divide the common term \((x-2)\). **Answer** \( \frac{x+2}{x-3} \)

**Common mistakes in simplifying rational expressions:**

When simplify rational expressions, you are only allowed to divide out common factors from the denominator but NOT common terms. For example, in the expression
we can cross out the \((x - 3)\) factor because \(\frac{x - 3}{x - 3} = 1\).

We write

\[
\frac{(x + 1) \cdot (x - 3)}{(x + 2) \cdot (x - 3)} \quad = \quad \frac{(x + 1)}{(x + 2)}
\]

However, don’t make the mistake of dividing out common \textbf{terms} in the numerator and denominator. For instance, in the expression.

\[
\frac{x^2 + 1}{x^2 - 5}
\]

we cannot cross out the \(x^2\) terms.

\[
\frac{x^2 + 1}{x^2 - 5} \neq \frac{x^2 + 1}{x^2 - 5}
\]

When we cross out terms that are part of a sum or a difference we are violating the order of operations (PEMDAS). We must remember that the fraction sign means division. When we perform the operation

\[
\frac{(x^2 + 1)}{(x^2 - 5)}
\]

we are dividing the numerator by the denominator

\[
(x^2 + 1) \div (x^2 - 5)
\]

The order of operations says that we must perform the operations inside the parenthesis before we can perform the division.

Try this with numbers:

\[
\frac{9 + 1}{9 - 5} = \frac{10}{4} = 2.5 \quad \text{But if we divide incorrectly we obtain the following} \quad \frac{9 + 1}{9 - 5} = \frac{10}{4} = -0.2.
\]

\textbf{CORRECT} \quad \textbf{INCORRECT}

\section*{Find Excluded Values of Rational Expressions}

Whenever a variable expression is present in the denominator of a fraction, we must be aware of the possibility that the denominator could be zero. Since division by zero is undefined, certain values of the variable must be \textbf{excluded}.
These values are the vertical asymptotes (i.e. values that cannot exist for \( x \)). For example, in the expression \( \frac{2}{x-3} \), the value of \( x = 3 \) must be excluded.

To find the excluded values we simply set the denominator equal to zero and solve the resulting equation.

**Example 2**

*Find the excluded values of the following expressions.*

a) \( \frac{x}{x+4} \)

b) \( \frac{2x+1}{x^2-x-6} \)

c) \( \frac{4}{x^2-5x} \)

**Solution**

a) When we set the denominator equal to zero we obtain. \( x + 4 = 0 \) \( \Rightarrow x = -4 \) is the excluded value.

b) When we set the denominator equal to zero we obtain. \( x^2 - x - 6 = 0 \)

Solve by factoring. \( (x - 3)(x + 2) = 0 \)

\( \Rightarrow x = 3 \) and \( x = -2 \) are the excluded values.

c) When we set the denominator equal to zero we obtain. \( x^2 - 5x = 0 \)

Solve by factoring. \( x(x - 5) = 0 \)

\( \Rightarrow x = 0 \) and \( x = 5 \) are the excluded values.

**Removable Zeros**

Notice that in the expressions in Example 1, we removed a division by zero when we simplified the problem. For instance,

\[
\frac{4x-2}{2x^2+x-1}
\]

was rewritten as

\[
\frac{2(2x-1)}{(2x-1)(x+1)}.
\]

This expression experiences division by zero when \( x = \frac{1}{2} \) and \( x = -1 \).

However, when we divide out common factors, we simplify the expression to \( \frac{2}{x+1} \). The reduced form allows the value \( x = \frac{1}{2} \). We thus removed a division by zero and the reduced expression has only \( x = -1 \) as the excluded value. Technically the original expression and the simplified expression are not the same. When we simplify to simplest form we should specify the removed excluded value. Thus,

\[
\frac{4x-2}{2x^2+x-1} = \frac{2}{x+1}, x \neq \frac{1}{2}
\]

The expression from Example 1, part \( b \) simplifies to

\[
\frac{x^2 - 2x + 1}{8x-8} = \frac{x - 1}{8}, x \neq 1
\]
The expression from Example 1, part c simplifies to

\[
\frac{x^2 - 4}{x^2 - 5x + 6} = \frac{x + 2}{x - 3}, \quad x \neq 2
\]

**Simplify Rational Models of Real-World Situations**

Many real world situations involve expressions that contain rational coefficients or expressions where the variable appears in the denominator.

**Example 3**

The gravitational force between two objects is given by the formula \( F = G \frac{m_1 m_2}{d^2} \). If the gravitation constant is \( G \approx 6.67 \times 10^{-11} \text{ (N} \cdot \text{m}^2/\text{kg}^2) \). The force of attraction between the Earth and the Moon is \( F = 2.0 \times 10^{20} \text{ N} \) (with masses of \( m_1 = 5.97 \times 10^{24} \text{ kg} \) for the Earth and \( m_2 = 7.36 \times 10^{22} \text{ kg} \) for the Moon).

**What is the distance between the Earth and the Moon?**

**Solution**

Let's start with the Law of Gravitation formula. \( F = G \frac{m_1 m_2}{d^2} \)

Now plug in the known values.

\[
2.0 \times 10^{20} \text{ N} = 6.67 \times 10^{-11} \frac{N \cdot m^2}{kg^2} \cdot \frac{(5.97 \times 10^{24} \text{ kg})(7.36 \times 10^{22} \text{ kg})}{d^2}
\]

Multiply the masses together.

\[
2.0 \times 10^{20} \text{ N} = 6.67 \times 10^{-11} \frac{N \cdot m^2}{kg^2} \cdot \frac{4.39 \times 10^{47} \text{ kg}^2}{d^2}
\]

Divide out the \( kg^2 \) units.

\[
2 \cdot 0 \times 10^{20} \text{ N} = 6.67 \times 10^{-11} \frac{N \cdot m^2}{kg^2} \cdot \frac{4.39 \times 10^{47} \text{ kg}^2}{d^2}
\]

Multiply the numbers in the numerator.

\[
2.0 \times 10^{20} \text{ N} = \frac{2.93 \times 10^{37} \text{ N} \cdot m^2}{d^2}
\]

Multiply both sides by \( d^2 \).

\[
2.0 \times 10^{20} \text{ N} \cdot d^2 = \frac{2.93 \times 10^{37} \text{ N} \cdot m^2}{d^2} \cdot d^2 \cdot N \cdot m^2
\]

Divide out common factors.

\[
2 \cdot 0 \times 10^{20} \text{ N} \cdot d^2 = \frac{2.93 \times 10^{37} \text{ N} \cdot m^2}{d^2} \cdot d^2 \cdot N \cdot m^2
\]

Simplify.

\[
2.0 \times 10^{20} \text{ N} \cdot d^2 = 2.93 \times 10^{37} \text{ N} \cdot m^2
\]

Divide both sides by \( 2.0 \times 10^{20} \text{ N} \).

\[
d^2 = \frac{2.93 \times 10^{37} \text{ N} \cdot m^2}{2.0 \times 10^{20} \text{ N}}
\]

Simplify.

\[
d^2 = 1.46 \times 10^{17} \text{ m}^2
\]

Take the square root of both sides.

\[
d = 3.84 \times 10^8 \text{ m}
\]

**Answer** The distance is \( 3.84 \times 10^8 \text{ m} \).

This is indeed the distance between the Earth and the Moon.

**Example 4**

The area of a circle is given by \( A = \pi r^2 \) and the circumference of a circle is given by \( C = 2\pi r \). Find the ratio of the circumference and area of the circle.

**Solution**

The ratio of the circumference and area of the circle is: \( \frac{2\pi r}{\pi r^2} \)
We divide out common factors from the numerator and denominator. \( \frac{2\pi^3 R}{\pi R^2} \).

Simplify.

**Answer** \( \frac{2}{R} \)

**Example 5**

The height of a cylinder is 2 units more than its radius. Find the ratio of the surface area of the cylinder to its volume.

![Diagram of a cylinder](image)

**Solution**

Define variables.

Let \( R \) = the radius of the base of the cylinder.

Then, \( R + 2 \) = the height of the cylinder.

To find the surface area of a cylinder, we need to add the areas of the top and bottom circle and the area of the curved surface.

\[
SA = \pi R^2 + \pi R^2 + 2\pi R(R + 2)
\]

The volume of a cylinder is the area of the base of the cylinder times its height, so:

\[
V = \pi R^2(R + 2)
\]

The ratio of the surface area of the cylinder to its volume is

\[
\frac{2\pi R^2 + 2\pi R(R + 2)}{\pi R^2(R + 2)}
\]

Distribute to eliminate the parentheses in the numerator.

Combine like terms in the numerator.

Factor common terms in the numerator.

Divide out common terms in the numerator and denominator.

Simplify.

\[
\frac{4\pi R^2 + 4\pi R}{\pi R^2(R + 2)} = \frac{4\pi R(R + 1)}{\pi R^2(R + 2)} = \frac{4(R + 1)}{R(R + 2)}\text{ Answer}
\]
2.4 Multiplication and Division of Rational Expressions

Learning Objectives

- Multiply rational expressions involving monomials.
- Multiply rational expressions involving polynomials.
- Multiply a rational expression by a polynomial.
- Divide rational expressions involving polynomials.
- Divide a rational expression by a polynomial.
- Solve real-world problems involving multiplication and division of rational expressions.

Introduction

The rules for multiplying and dividing rational expressions are the same as the rules for multiplying and dividing rational numbers. Let’s start by reviewing multiplication and division of fractions. When we multiply two fractions we multiply the numerators and denominators separately:

\[
\frac{a}{b} \cdot \frac{c}{d} = \frac{a \cdot c}{b \cdot d}
\]

When we divide two fractions we first change the operation to multiplication. Remember that division is the inverse operation of multiplication, or you can think that division is the same as multiplication by the reciprocal of the number.

\[
\frac{a}{b} \div \frac{c}{d} = \frac{a}{b} \cdot \frac{d}{c}
\]

The problem is completed by multiplying the numerators and denominators separately \( \frac{a \cdot d}{b \cdot c} \).

Multiply Rational Expressions Involving Monomials

Example 1

Multiply \( \frac{4}{5} \cdot \frac{15}{8} \).

Solution

We follow the multiplication rule and multiply the numerators and the denominators separately.

\[
\frac{4}{5} \cdot \frac{15}{8} = \frac{4 \cdot 15}{5 \cdot 8} = \frac{60}{40}
\]

Notice that the answer is not in simplest form. We can divide out a common factor of 20 from the numerator and denominator of the answer.
We could have obtained the same answer a different way: by dividing out common factors \textit{before} multiplying.

\[
\frac{4 \cdot 15}{5 \cdot 8} = \frac{4 \cdot 15}{5 \cdot 8}
\]

We can divide out a factor of 4 from the numerator and denominator:

\[
\frac{4 \cdot 15}{5 \cdot 8} = \frac{4 \cdot 15}{5 \cdot 8}
\]

We can also divide out a factor of 5 from the numerator and denominator:

\[
\frac{1 \cdot 15}{5 \cdot 2} = \frac{1 \cdot 15}{5 \cdot 2} = \frac{1 \cdot 3}{1 \cdot 2} = \frac{3}{2}
\]

\textbf{Answer:} The final answer is \(\frac{3}{2}\), no matter which you you go to arrive at it.

Multiplying rational expressions follows the same procedure.

- Divide out common factors from the numerators and denominators of the fractions.
- Multiply the leftover factors in the numerator and denominator.

\textbf{Example 2}

\textit{Multiply the following} \(\frac{a}{16b^8} \cdot \frac{4b^3}{5a^2}\).

\textbf{Solution}

Divide out common factors from the numerator and denominator.

\[
\frac{a^1}{16b^8} \cdot \frac{4b^3}{5a^2} = \frac{4}{5} \cdot \frac{1}{16b^5} = \frac{1}{20ab^5}
\]

When we multiply the left-over factors, we get

\[
\frac{1}{20ab^5} \text{ Answer}
\]

\textbf{Example 3}

\textit{Multiply} \(9x^3 \cdot \frac{4y^2}{21x^4}\).

\textbf{Solution}

Rewrite the problem as a product of two fractions.
2.4. Multiplication and Division of Rational Expressions

\[
\frac{9x^2}{1} \cdot \frac{4y^2}{21x^4}
\]

Divide out common factors from the numerator and denominator

\[
\frac{9^3x^{2+1}}{1} \cdot \frac{4y^2}{21x^4x^2}
\]

We multiply the left-over factors and get

\[
\frac{12y^2}{7x^2} \quad \text{Answer}
\]

Multiply Rational Expressions Involving Polynomials

When multiplying rational expressions involving polynomials, the first step involves factoring all polynomial expressions as much as we can. We then follow the same procedure as before.

Example 4

Multiply \(\frac{4x+12}{3x^2} \cdot \frac{x}{x^2-9}\).

Solution

Factor all polynomial expressions where possible.

\[
\frac{4(x+3)}{3x^2} \cdot \frac{x}{(x+3)(x-3)}
\]

Divide out common factors in the numerator and denominator of the fractions:

\[
\frac{4(x+3)^1}{3x^2x} \cdot \frac{x^1}{(x+3)(x-3)}
\]

The simplified product in factored form is:

\[
\frac{4}{3x(x-3)}
\]

(Optional) Multiply the left-over factors.

\[
\frac{4}{3x(x-3)} = \frac{4}{3x^2-9x} \quad \text{Answer}
\]

Example 5

Multiply \(\frac{12x^2-x-6}{x^2-1} \cdot \frac{x^2+7x+6}{4x^2-27x+18}\). 

70
Solution

Factor all polynomial expression where possible.

\[
\frac{(3x + 2)(4x - 3)}{(x + 1)(x - 1)} \cdot \frac{(x + 1)(x + 6)}{(4x - 3)(x - 6)}
\]

Divide out common factors in the numerator and denominator of the fractions.

\[
\frac{(3x + 2)(4x - 3)}{(x + 1)(x - 1)} \cdot \frac{(x + 1)(x + 6)}{(4x - 3)(x - 6)}
\]

The simplified product in factored form is:

\[
\frac{(3x + 2)(x + 6)}{(x - 1)(x - 6)}
\]

(Optional) Multiply the remaining factors.

\[
\frac{(3x + 2)(x + 6)}{(x - 1)(x - 6)} = \frac{3x^2 + 20x + 12}{x^2 - 7x + 6} \text{ Answer}
\]

Multiply a Rational Expression by a Polynomial

When we multiply a rational expression by a whole number or a polynomial, we must remember that we can write the whole number (or polynomial) as a fraction with denominator equal to one. We then proceed the same way as in the previous examples.

Example 6

Multiply \(\frac{3x + 18}{4x^2 + 19x - 5} \cdot (x^2 + 3x - 10)\).

Solution

Rewrite the expression as a product of fractions.

\[
\frac{3x + 18}{4x^2 + 19x - 5} \cdot \frac{x^2 + 3x - 10}{1}
\]

Factor all polynomials possible and cancel common factors.

\[
\frac{3(x + 6)}{(x + 5)^2(4x - 1)} \cdot \frac{(x - 2)(x + 5)}{1}
\]

The simplified product in factored form is:

\[
\frac{3(x + 6)(x - 2)}{(4x - 1)}
\]
2.4. Multiplication and Division of Rational Expressions

(Optional) Multiply the remaining factors.

\[
\frac{(3x + 18)(x - 2)}{4x - 1} = \frac{3x^2 + 12x - 36}{4x - 1}
\]

Divide Rational Expressions Involving Polynomials

Since division is the reciprocal of the multiplication operation, we first rewrite the division problem as a multiplication problem and then proceed with the multiplication as outlined in the previous example.

Note: Remember that \( \frac{a}{b} \div \frac{c}{d} = \frac{a}{b} \cdot \frac{d}{c} \). The first fraction remains the same and you take the reciprocal of the second fraction. Do not fall in the common trap of flipping the first fraction.

Example 7
Divide \( \frac{4x^2}{15} \div \frac{6x}{5} \).

Solution
First convert the division problem into a multiplication problem by flipping what we are dividing by and then simplify as usual.

\[
\frac{4x^2}{15} \div \frac{6x}{5} = \frac{4x^2}{15} \cdot \frac{5}{6x} = \frac{2x}{3} \cdot \frac{1}{3} = \frac{2x}{9}
\]

Example 8
Divide \( \frac{3x^2 - 15x}{2x^2 + 3x - 14} \div \frac{x^2 - 25}{2x^2 + 13x + 21} \).

Solution
First convert into a multiplication problem by flipping what we are dividing by and then simplify as usual.

\[
\frac{3x^2 - 15x}{2x^2 + 3x - 14} \cdot \frac{2x^2 + 13x + 21}{x^2 - 25}
\]

Factor all polynomials and divide out common factors.

\[
\frac{3x(x - 5)}{(2x + 7)(x + 3)} \cdot \frac{(2x + 7)(x - 2)}{(x - 5)(x + 5)}
\]

The simplified product in factored form is:

\[
\frac{3x(x + 3)}{(x - 2)(x + 5)}
\]

(Optional) Multiply the factors.

\[
\frac{3x(x + 3)}{(x - 2)(x + 5)} = \frac{3x^2 + 9x}{x^2 + 3x - 10}
\]
Divide a Rational Expression by a Polynomial

When we divide a rational expression by a whole number or a polynomial, we must remember that we can write the whole number (or polynomial) as a fraction with denominator equal to one. We then proceed the same way as in the previous examples.

**Example 9**

*Divide* \( \frac{9x^2 - 4}{2x - 2} \div (21x^2 - 2x - 8) \).

**Solution**

Rewrite the expression as a division of fractions.

\[
\frac{9x^2 - 4}{2x - 2} \div \frac{21x^2 - 2x - 8}{1}
\]

Convert into a multiplication problem by taking the reciprocal of the divisor (i.e. what we are dividing by).

\[
\frac{9x^2 - 4}{2x - 2} \cdot \frac{1}{21x^2 - 2x - 8}
\]

Factor all polynomials and divide out common factors.

\[
\frac{(3x - 2)(3x + 2)}{2(x - 1)} \cdot \frac{1}{(3x - 2)(7x + 4)}
\]

The simplified quotient in factored for is:

\[
\frac{3x^2}{2(x - 1)}
\]

(Optional) Multiply the remaining factors.

\[
\frac{3x + 2}{14x^2 - 6x - 8}
\]

**Solve Real-World Problems Involving Multiplication and Division of Rational Expressions**

**Example 10**

Suppose Marciel is training for a running race. Marciel’s speed (in miles per hour) of his training run each morning is given by the function \(0.1(x^3 - 9x)\), where \(x\) is the number of bowls of cereal he had for breakfast \((4 \leq x \leq 6)\). Marciel’s training distance (in miles), if he eats \(x\) bowls of cereal, is \(0.1(3x^2 - 9x)\). What is the function for Marciel’s time and how long does it take Marciel to do his training run if he eats five bowls of cereal on Tuesday morning?

**Solution**
time = \frac{distance}{speed}

\begin{align*}
time &= \frac{3x^2 - 9x}{x^3 - 9x} = \frac{0.3x(x - 3)}{0.1x(x^2 - 9)} = \frac{0.3x(x - 3)}{0.1x(x + 3)(x - 3)} \\
time &= \frac{3}{x + 3}
\end{align*}

If \( x = 5 \), then

\begin{align*}
time &= \frac{3}{5 + 3} = \frac{3}{8}
\end{align*}

**Answer** Marciel will run for \( \frac{3}{8} \) of an hour.
Addition and Subtraction of Rational Expressions

Learning Objectives

- Add and subtract rational expressions with the same denominator.
- Find the least common denominator of rational expressions.
- Add and subtract rational expressions with different denominators.
- Solve real-world problems involving addition and subtraction of rational expressions.

Introduction

Like fractions, rational expressions represent a portion of a quantity. Remember that when we add or subtract fractions we must first make sure that they have the same denominator. Once the fractions have the same denominator, we combine the different portions by adding or subtracting the numerators and writing that answer over the common denominator.

Add and Subtract Rational Expressions with the Same Denominator

Fractions with common denominators combine in the following manner.

\[
\frac{a}{c} + \frac{b}{c} = \frac{a + b}{c} \quad \text{and} \quad \frac{a}{c} - \frac{b}{c} = \frac{a - b}{c}
\]

Example 1

Simplify.

a) \( \frac{8}{7} - \frac{2}{7} + \frac{4}{7} \)

b) \( \frac{4x^2 - 3}{x + 5} + \frac{2x^2 - 1}{x + 5} \)

c) \( \frac{x^2 - 2x + 1}{2x + 3} - \frac{3x^2 - 3x + 5}{2x + 3} \)

Solution

a) Since the denominators are the same we combine the numerators.

\[
\frac{8}{7} - \frac{2}{7} + \frac{4}{7} = \frac{8 - 2 + 4}{7} = \frac{10}{7} \quad \text{Answer}
\]

b) Since the denominators are the same we combine the numerators.

\[
\frac{4x^2 - 3 + 2x^2 - 1}{x + 5}
\]

Simplify by collecting like terms.
c) Since the denominators are the same we combine the numerators. Make sure the subtraction sign is distributed to all terms in the second expression.

\[
\frac{6x^2 - 4}{x + 5} \quad \text{Answer}
\]

\[
\frac{(x^2 - 2x + 1) - (3x^2 - 3x + 5)}{2x + 3} = \frac{x^2 - 2x + 1 - 3x^2 + 3x - 5}{2x + 3} = \frac{-2x^2 + x - 4}{2x + 3} \quad \text{Answer}
\]

**Find the Least common Denominator of Rational Expressions**

To add and subtract fractions with different denominators, we must first rewrite all fractions so that they have the same denominator. In general, we want to find the least common denominator. To find the least common denominator, we find the least common multiple (LCM) of the expressions in the denominators of the different fractions. Remember that the least common multiple of two or more integers is the least positive integer having each as a factor.

Consider the integers 234, 126 and 273.

To find the least common multiple of these numbers we write each integer as a product of its prime factors.

Here we present a systematic way to find the prime factorization of a number.

- Try the prime numbers, in order, as factors.
- Use repeatedly until it is no longer a factor.
- Then try the next prime:

\[
234 = 2 \cdot 117 \\
\quad = 2 \cdot 3 \cdot 39 \\
\quad = 2 \cdot 3 \cdot 3 \cdot 13 \\
\quad 234 = 2 \cdot 3^2 \cdot 13
\]

\[
126 = 2 \cdot 63 \\
\quad = 2 \cdot 3 \cdot 21 \\
\quad = 2 \cdot 3 \cdot 3 \cdot 7 \\
\quad 126 = 2 \cdot 3^2 \cdot 7
\]

\[
273 = 3 \cdot 91 \\
\quad = 3 \cdot 7 \cdot 13
\]
Once we have the prime factorization of each number, the least common multiple of the numbers is the product of all the different factors taken to the highest power that they appear in any of the prime factorizations. In this case, the factor of two appears at most once, the factor of three appears at most twice, the factor of seven appears at most once, the factor of 13 appears at most once. Therefore,

$$\text{LCM} = 2 \cdot 3^2 \cdot 7 \cdot 13 = 1638$$ Answer

If we have integers that have no common factors, the least common multiple is just the product of the integers. Consider the integers 12 and 25.

$$12 = 2^2 \cdot 3 \quad \text{and} \quad 25 = 5^2$$

The \( \text{LCM} = 2^2 \cdot 3 \cdot 5^2 = 300 \), which is just the product of 12 and 25.

The procedure for finding the least common multiple of polynomials is similar. We rewrite each polynomial in factored form and we form the LCM by taken each factor to the highest power it appears in any of the separate expressions.

**Example 2**

*Find the LCM of \( 48x^2y \) and \( 60xy^3z \).*

**Solution**

First rewrite the integers in their prime factorization.

$$48 = 2^4 \cdot 3$$
$$60 = 2^2 \cdot 3 \cdot 5$$

Therefore, the two expressions can be written as

$$48x^2y = 2^4 \cdot 3 \cdot x^2 \cdot y$$
$$60xy^3z = 2^2 \cdot 3 \cdot 5 \cdot x \cdot y^3 \cdot z$$

The LCM is found by taking each factor to the highest power that it appears in either expression.

$$\text{LCM} = 2^4 \cdot 3 \cdot 5 \cdot x^2 \cdot y^3 \cdot z = 240x^2y^3z.$$ 

**Example 3**

*Find the LCM of \( 2x^2 + 8x + 8 \) and \( x^3 - 4x^2 - 12 \).*

**Solution**

Factor the polynomials completely.

$$2x^2 + 8x + 8 = 2(x^2 + 4x + 4) = 2(x + 2)^2$$
$$x^3 - 4x^2 - 12x = x(x^2 - 4x - 12) = x(x - 6)(x + 2)$$
The LCM is found by taking each factor to the highest power that it appears in either expression.

$$\text{LCM} = 2x(x+2)^2(x-6) \text{ Answer}$$

It is customary to leave the LCM in factored form because this form is useful in simplifying rational expressions and finding any excluded values.

**Example 4**

Find the LCM of \(x^2 - 25\) and \(x^2 + 3x + 2\).

**Solution**

Factor the polynomials completely:

\[
x^2 - 25 = (x+5)(x-5)
\]
\[
x^2 + 3x + 2 = (x+2)(x+1)
\]

Since the two expressions have no common factors, the LCM is just the product of the two expressions.

$$\text{LCM} = (x+5)(x-5)(x+2)(x+1) \text{ Answer}$$

**Add and Subtract Rational Expressions with Different Denominators**

Now we are ready to add and subtract rational expressions. We use the following procedure.

1. Find the least common denominator (LCD) of the fractions.
2. Express each fraction as an equivalent fraction with the LCD as the denominator.
3. Add or subtract and simplify the result.

**Example 5**

Add \(\frac{4}{12} + \frac{5}{18}\).

**Solution**

We can write the denominators in their prime factorization \(12 = 2^2 \cdot 3\) and \(18 = 2 \cdot 3^2\). The least common denominator of the fractions is the LCM of the two numbers: \(2^2 \cdot 3^2 = 36\). Now we need to rewrite each fraction as an equivalent fraction with the LCD as the denominator.

**For the first fraction.** \(12\) needs to be multiplied by a factor of \(3\) in order to change it into the LCD, so we multiply the numerator and the denominator by \(3\).

\[
\frac{4}{12} \cdot \frac{3}{3} = \frac{12}{36}
\]

**For the second fraction.** \(18\) needs to be multiplied by a factor of \(2\) in order to change it into the LCD, so we multiply the numerator and the denominator by \(2\).

\[
\frac{5}{18} \cdot \frac{2}{2} = \frac{10}{36}
\]
Once the denominators of the two fractions are the same we can add the numerators.

\[
\frac{12}{36} + \frac{10}{36} = \frac{22}{36}
\]

The answer can be simplified by dividing out a common factor of 2.

\[
\frac{12}{36} + \frac{10}{36} = \frac{22}{36} = \frac{11}{18} \quad \text{Answer}
\]

**Example 6**

*Perform the following operation and simplify.*

\[
\frac{2}{x+2} - \frac{3}{2x-5}
\]

**Solution**

The denominators cannot be factored any further, so the LCD is just the product of the separate denominators.

\[
\text{LCD} = (x+2)(2x-5)
\]

The first fraction needs to be multiplied by the factor \((2x-5)\) and the second fraction needs to be multiplied by the factor \((x+2)\).

\[
\frac{2}{x+2} \cdot \frac{(2x-5)}{(2x-5)} - \frac{3}{2x-5} \cdot \frac{(x+2)}{(x+2)}
\]

We combine the numerators and simplify.

\[
\frac{2(2x-5) - 3(x+2)}{(x+2)(2x-5)} = \frac{4x - 10 - 3x - 6}{(x+2)(2x-5)}
\]

Combine like terms in the numerator.

\[
\frac{x-16}{(x+2)(2x-5)} \quad \text{Answer}
\]

**Example 8**

*Perform the following operation and simplify.*

\[
\frac{4x}{x-5} - \frac{3x}{5-x}
\]
Solution
Notice that the denominators are almost the same. They differ by a factor of -1.
Factor a $-1$ from the terms in the second denominator.

\[ \frac{4x}{x - 5} - \frac{3x}{(x - 5)} \]

Notice we are now subtracting a negative. Remember subtracting a negative is equivalent to adding a positive. In general, $a - (-b) = a + b$. We can write the difference as an equivalent sum.

\[ \frac{4x}{x - 5} + \frac{3x}{(x - 5)} \]

Since the denominators are the same we combine the numerators.

\[ \frac{4x + 3x}{(x - 5)} = \frac{7x}{x - 5} \text{ Answer} \]

Example 9
Perform the following operation and simplify.

\[ \frac{2x - 1}{x^2 - 6x + 9} - \frac{3x + 4}{x^2 - 9} \]

Solution
We factor the denominators.

\[ \frac{2x - 1}{(x - 3)^2} - \frac{3x + 4}{(x + 3)(x - 3)} \]

The LCD is the product of all the different factors taken to the highest power they have in either denominator. LCD = $(x - 3)^2(x + 3)$.

The first fraction needs to be multiplied by a factor of $(x + 3)$ and the second fraction needs to be multiplied by a factor of $(x - 3)$.

\[ \frac{2x - 1}{(x - 3)^2} \cdot \frac{(x + 3)}{(x + 3)} - \frac{3x + 4}{(x + 3)(x - 3)} \cdot \frac{(x - 3)}{(x - 3)} \]

Combine the numerators.

\[ \frac{(2x - 1)(x + 3) - (3x + 4)(x - 3)}{(x - 3)^2(x + 3)} \]

Eliminate all parentheses in the numerator.
\[
\frac{(2x^2 + 5x) - 3 - (3x^2 - 5x - 12)}{(x - 3)^2(x + 3)}
\]

Distribute the negative sign in the second parenthesis.

\[
\frac{2x^2 + 5x - 3 - 3x^2 + 5x + 12}{(x - 3)^2(x + 3)}
\]

Combine like terms in the numerator.

\[
\frac{-x^2 + 10x + 9}{(x - 3)^2(x + 3)} \quad \text{Answer}
\]

**Solve Real-World Problems Involving Addition and Subtraction of Rational Expressions**

**Example 10**

*In an electrical circuit with two resistors placed in parallel, the reciprocal of the total resistance is equal to the sum of the reciprocals of each resistance* \( \frac{1}{R_{\text{tot}}} = \frac{1}{R_1} + \frac{1}{R_2} \). *Find an expression for the total resistance in a circuit with two resistors wired in parallel.*

**Solution**

The equation for the relationship between total resistance and resistances placed in parallel says that the reciprocal of the total resistance is the sum of the reciprocals of the individual resistances.

Let's simplify the expression \( \frac{1}{R_1} + \frac{1}{R_2} \).

The lowest common denominator is

\[
= R_1R_2
\]

Multiply the first fraction by \( \frac{R_2}{R_2} \) and the second fraction by \( \frac{R_1}{R_1} \).

\[
\frac{R_2}{R_2} \cdot \frac{1}{R_1} + \frac{R_1}{R_1} \cdot \frac{1}{R_2}
\]

Simplify.

\[
\frac{R_2 + R_1}{R_1R_2}
\]

So we have:

\[
\frac{1}{R_{\text{tot}}} = \frac{R_1 + R_2}{R_1R_2}
\]
Therefore, the total resistance is the reciprocal of this expression.

\[ R_{\text{tot}} = \frac{R_1 R_2}{R_1 + R_2} \quad \text{Answer} \]

**Number Problems**

These problems express the relationship between two numbers.

**Example 11**

*The sum of a number and its reciprocal is \( \frac{53}{14} \). Find the numbers.*

**Solution**

1. **Define variables.**

Let \( x = \) a number

Then, \( \frac{1}{x} \) is the reciprocal of the number

2. **Set up an equation.**

The equation that describes the relationship between the numbers is:

\[ x + \frac{1}{x} = \frac{53}{14} \]

3. **Solve the equation.**

Multiply the first term by \( \frac{x}{x} \). The second term already has a denominator of \( x \) and requires no additional multiplication. We get:

\[ \frac{x}{x} \cdot x + \frac{1}{x} = \frac{53}{14} \]

Simplify the expression on the left side of the equation.

\[ \frac{x^2 + 1}{x} = \frac{53}{14} \]

Because the rational expressions are equal, they are proportional. Therefore, we can cross multiply to form an equivalent equation.

\[ 14(x^2 + 1) = 53x \]

Simplify.

\[ 14x^2 + 14 = 53x \]

Write all terms on one side of the equation.
14x^2 - 53x + 14 = 0

Factor.

\((7x - 2)(2x - 7) = 0\)

\[x = \frac{2}{7}\ \text{and } x = \frac{7}{2}\]

Notice there are two answers for \(x\), but they are really the same. One answer represents the number and the other answer represents its reciprocal.

4. Check. \(\frac{2}{7} + \frac{7}{2} = \frac{4 + 49}{14} = \frac{53}{14}\). The answer checks out.

Work Problems

These are problems where two people or two machines work together to complete a job. Work problems often contain rational expressions. Typically we set up such problems by looking at the part of the task completed by each person or machine. The completed task is the sum of the parts of the tasks completed by each individual or each machine.

Part of task completed by first person + Part of task completed by second person = One completed task

To determine the part of the task completed by each person or machine we use the following fact.

Part of the task completed = rate of work \times time spent on the task

In general, it is very useful to set up a table where we can list all the known and unknown variables for each person or machine and then combine the parts of the task completed by each person or machine at the end.

Example 12

Mary can paint a house by herself in 12 hours. John can paint a house by himself in 16 hours. How long would it take them to paint the house if they worked together?

Solution:

1. Define variables.

Let \(t\) = the time it takes Mary and John to paint the house together.

2. Construct a table.

Since Mary takes 12 hours to paint the house by herself, in one hour she paints \(\frac{1}{12}\) of the house.

Since John takes 16 hours to pain the house by himself, in one hour he paints \(\frac{1}{16}\) of the house.

Mary and John work together for \(t\) hours to paint the house together. Using,

Part of the task completed = rate of work \times time spent on the task times the amount of time spend on the task.

we can write that Mary completed \(\frac{t}{12}\) of the house and John completed \(\frac{t}{16}\) of the house in this time.

This information is nicely summarized in the table below:

<table>
<thead>
<tr>
<th>Painter</th>
<th>Rate of work (per hour)</th>
<th>Time worked</th>
<th>Part of Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mary</td>
<td>(\frac{1}{12})</td>
<td>(t)</td>
<td>(\frac{t}{12})</td>
</tr>
<tr>
<td>John</td>
<td>(\frac{1}{16})</td>
<td>(t)</td>
<td>(\frac{t}{16})</td>
</tr>
</tbody>
</table>
3. Set up an equation.
Since Mary completed $\frac{t}{12}$ of the house and John completed $\frac{t}{16}$ and together they paint the whole house in $t$ hours, we can write the equation

$$\frac{t}{12} + \frac{t}{16} = 1.$$

4. Solve the equation.
Find the lowest common denominator of the expression on the left side of the equation.

$$\text{LCD} = 48$$

Multiply all terms in the equation by the LCM.

$$48 \cdot \frac{t}{12} + 48 \cdot \frac{t}{16} = 48 \cdot 1$$

Cancel common factors in each term.

$$48 \cdot \frac{4}{12} + 48 \cdot \frac{3}{16} = 48 \cdot 1$$

Simplify.

$$4t + 3t = 48$$

$$7t = 48$$

$$t = \frac{48}{7}$$

$$t \approx 6.86 \text{ hours}$$

Check
The answer is reasonable. We expect the job to take more than half the time Mary takes but less than half the time John takes since Mary works faster than John.

Example 12
Suzie and Mike take two hours to mow a lawn when they work together. It takes Suzie 3.5 hours to mow the same lawn if she works by herself. How long would it take Mike to mow the same lawn if he worked alone?

Solution
1. Define variables.
Let $t$ = the time it takes Mike to mow the lawn by himself.

2. Construct a table.
**Table 2.8:**

<table>
<thead>
<tr>
<th>Painter</th>
<th>Rate of Work (per Hour)</th>
<th>Time Worked</th>
<th>Part of Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Suzie</td>
<td>$\frac{1}{5} = \frac{7}{4}$</td>
<td>2</td>
<td>$\frac{4}{7}$</td>
</tr>
<tr>
<td>Mike</td>
<td>$\frac{1}{7}$</td>
<td>2</td>
<td>$\frac{2}{7}$</td>
</tr>
</tbody>
</table>

3. **Set up an equation.**

Since Suzie completed $\frac{4}{7}$ of the lawn and Mike completed $\frac{2}{7}$ of the lawn and together they mow the lawn in 2 hours, we can write the equation: $\frac{4}{7} + \frac{2}{7} = 1$.

4. **Solve the equation.**

Find the lowest common denominator.

$$\text{LCM} = 7t$$

Multiply all terms in the equation by the LCM.

$$7t \cdot \frac{4}{7} + 7t \cdot \frac{2}{7} = 7t \cdot 1$$

Cancel common factors in each term.

$$7t \cdot \frac{4}{7} + 7t \cdot \frac{2}{7} = 7t \cdot 1$$

Simplify.

$$4t + 14 = 7t$$

$$3t = 14 \Rightarrow t = \frac{14}{3} = 4 \frac{2}{3} \text{ hours Answer}$$

**Check.**

The answer is reasonable. We expect Mike to work slower than Suzie because working by herself it takes her less than twice the time it takes them to work together.
2.6 Complex Rational Fractions

A complex rational expression (complex fraction) is a rational expression of the form \( \frac{\frac{A}{B}}{\frac{C}{D}} \)
whose numerator and/or denominator is also a rational expression. In other words, it is a fraction divided by a fraction.

Examples of complex rational expressions:

\[
\frac{2}{\frac{x}{5}} = \frac{\frac{x-1}{3x}}{\frac{2}{x^2 + x^3}} = \frac{\frac{x^2 - 4}{x^2 - 2x - 1}}{\frac{x - 3}{x - 3}}
\]

### Simplifying Complex Expressions Method 1

**Good for Complex fractions of the type:**

\[
\frac{\frac{A}{B}}{\frac{C}{D}}
\]

1. Simplify the numerator and denominator of the complex expression so that each has only rational expression (fraction).
2. Use the definition of division to rewrite as multiplication

\[
\frac{\frac{A}{B}}{\frac{C}{D}} = \frac{A}{B} \div \frac{C}{D} = \frac{A}{B} \cdot \frac{D}{C} = \frac{AD}{BC}
\]
3. Factor the numerator and denominator and simplify.

**Examples:**

\[
\frac{\frac{y^4}{12}}{\frac{\frac{y}{6}}{12}} = \frac{\frac{y^4}{12} \div \frac{y}{6}}{\frac{y}{12}} = \frac{\frac{y^4}{12} \cdot \frac{6}{y}}{\frac{y}{12}} = \frac{\frac{y^3}{2}}{1}
\]

\[
\frac{\frac{3x^2 + 6x + 3}{5x}}{\frac{9x + 9}{10x^2}} = \frac{\frac{3x^2 + 6x + 3}{5x} \div \frac{9x + 9}{10x^2}}{\frac{5x}{9x + 9}} = \frac{\frac{3x^2 + 6x + 3}{5x} \cdot \frac{10x^2}{9x + 9}}{\frac{5x}{9x + 9}} = \frac{\frac{x(3x + 1)(x + 1)}{5}}{\frac{2x^2(x + 1)}{3}} = \frac{2x(x + 1)}{3}
\]
Simplifying Complex Expressions Method 2
Good for Complex fractions of the type:
\[
\frac{A}{B} + \frac{C}{D} = \frac{E}{F} + \frac{G}{H}
\]

1. Find the LCD of each fraction. (factor if necessary).
2. Multiply each term in the numerator and denominator by the LCD.
3. Simplify

Examples:

\[
\frac{1}{x} + \frac{1}{2} = \frac{1}{x^2} - \frac{1}{4}
\]
The LCD of \(\frac{1}{x}, \frac{1}{2}, \frac{1}{x^2}, \) and \(\frac{1}{4}\) is \(4x^2\)

\[
\frac{1}{x} + \frac{1}{2} = \frac{4x^2}{x^2 - 4}
\]
The LCD is \((x-3)(x-2)\)

\[
\frac{2}{x-3} + \frac{5}{x-2} = \frac{2(x-2)(x-3) + 5(x-3)(x-2)}{3(x-3)(x-2)}
\]

\[
\frac{2}{x-2} + \frac{5}{x-3} = \frac{2x-4 + 5x-15}{3x-9 - 4x + 8} = \frac{7x-19}{-x+1}
\]
2.7 Solutions of Rational Equations.

Learning Objectives

- Solve rational equations using cross products.
- Solve rational equations using lowest common denominators.
- Solve real-world problems with rational equations.

Introduction

A rational equation is one that contains rational expressions. It can be an equation that contains rational coefficients or an equation that contains rational terms where the variable appears in the denominator.

An example of the first kind of equation is \( \frac{3}{5}x + \frac{1}{2} = 4 \).

An example of the second kind of equation is \( \frac{x}{x-1} + 1 = \frac{4}{2x+3} \).

The first aim in solving a rational equation is to eliminate all denominators. In this way, we can change a rational equation to a polynomial equation which we can solve with the methods we have learned this far.

Solve Rational Equations Using Cross Products

A rational equation that contains two terms is easily solved by the method of cross products or cross multiplication. Consider the following equation.

\[
\frac{x}{5} = \frac{x + 1}{2}
\]

Our first goal is to eliminate the denominators of both rational expressions. In order to remove the five from the denominator of the first fraction, we multiply both sides of the equation by five:

\[
5 \cdot \frac{x}{5} = \frac{x + 1}{2} \cdot 5
\]

Now, we remove the 2 from the denominator of the second fraction by multiplying both sides of the equation by two.

\[
2 \cdot x = \frac{5(x + 1)}{2}
\]

The equation simplifies to \( 2x = 5(x + 1) \). Continuing we get:

\[
2x = 5x + 5 \Rightarrow x = -\frac{5}{3} \quad \text{Answer}
\]

Notice that when we remove the denominators from the rational expressions we end up multiplying the numerator on one side of the equal sign with the denominator of the opposite fraction.
Once again, we obtain the simplified equation: $2x = 5(x + 1)$, whose solution is $x = -\frac{5}{3}$.

We check the answer by plugging the answer back into the original equation.

**Check**

On the left-hand side, if $x = -\frac{5}{3}$, then we have

$$\frac{x}{5} = \frac{-\frac{5}{3}}{5} = -\frac{1}{3}$$

On the right hand side, we have

$$\frac{x + 1}{2} = \frac{-\frac{5}{3} + 1}{2} = \frac{-\frac{2}{3}}{2} = -\frac{1}{3}$$

Since the two expressions are equal, the answer checks out.

**Example 1**

Solve the equation $\frac{2}{x-2} = \frac{3}{x+3}$.

**Solution**

Use cross-multiplication to eliminate the denominators of both fractions.

The equation simplifies to

$$2(x + 3) = 3(x - 2)$$

Simplify.

$$2x + 6 = 3x - 6$$

$$x = 12$$

**Check.**

$$\frac{2}{x-2} = \frac{2}{12-2} = \frac{2}{10} = \frac{1}{5}$$

$$\frac{3}{x+3} = \frac{3}{12+3} = \frac{3}{15} = \frac{1}{5}$$

The answer checks out because the expressions are equal.
2.7. Solutions of Rational Equations.

Example 2

Solve the equation \( \frac{2x^2}{x+4} = \frac{5}{x} \).

Solution

Cross-multiply.

\[
\frac{2x}{x+4} \cdot \frac{5}{x} = \]

The equation simplifies to

\[2x^2 = 5(x + 4)\]

Simplify.

\[2x^2 = 5x + 20\]

Move all terms to one side of the equation.

\[2x^2 - 5x - 20 = 0\]

Notice that this equation has a degree of two, that is, it is a \textit{quadratic equation}. We can solve it using the quadratic formula.

\[x = \frac{5 \pm \sqrt{185}}{4} \Rightarrow x \approx -2.15 \text{ or } x \approx 4.65\]

Answer

It is important to check the answer in the original equation when the variable appears in any denominator of the equation because the answer might be an excluded value of any of the rational expression. If the answer obtained makes any denominator equal to zero, that value is not a solution to the equation.

Check:

First we check \( x \approx -2.15 \) by substituting it in the original equations. On the left hand side we get the following.

\[
\frac{2(-2.15)}{-2.15 + 4} = \frac{-4.30}{1.85} \approx -2.3
\]

Now, check on the right hand side.

\[
\frac{5}{-2.15} \approx -2.3
\]

Thus, 2.15 checks out.

For \( x \approx 4.65 \) we repeat the procedure.
\[
\frac{2x}{x+4} = \frac{2(4.65)}{4.65+4} \approx 1.08.
\]
\[
\frac{5}{x} = \frac{5}{4.65} \approx 1.08.
\]

4.65 also checks out.

**Solve Rational Equations Using the Lowest Common Denominators**

An alternate way of eliminating the denominators in a rational equation is to multiply all terms in the equation by the lowest common denominator. This method is suitable even when there are more than two terms in the equation.

**Example 3**

Solve \( \frac{3x}{35} = \frac{x^2}{5} - \frac{1}{21} \).

**Solution**

Find the lowest common denominator of all the terms in the equation.

LCD = 105

Multiply each term by the LCD.

\[105 \cdot \frac{3x}{35} = 105 \cdot \frac{x^2}{5} - 105 \cdot \frac{1}{21}\]

Divide out common factors.

\[105 \cdot \frac{3x}{35} = 105 \cdot \frac{x^2}{5} - 105 \cdot \frac{5}{21}\]

The equation simplifies to

\[9x = 21x^2 - 5\]

Move all terms to one side of the equation.

\[21x^2 - 9x - 5 = 0\]

Solve using the quadratic formula.

\[x = \frac{9 \pm \sqrt{501}}{42}\]

\[x \approx -0.32 \text{ or } x \approx 0.75 \text{ Answer}\]

**Check**
We use the substitution $x \approx -0.32$.

$$\frac{3x}{35} = \frac{3(-0.32)}{35} \approx -0.027$$

$$\frac{x^2}{5} - \frac{1}{24} = \frac{(-0.32)^2}{5} - \frac{1}{21} \approx -0.027. \text{ The answer checks out.}$$

Now we check the solution $x \approx 0.75$.

$$\frac{3x}{35} = \frac{3(0.75)}{35} \approx 0.064$$

$$\frac{x^2}{5} - \frac{1}{24} = \frac{(0.75)^2}{5} - \frac{1}{21} \approx 0.064. \text{ The answer checks out.}$$

**Example 4**

_Solve_ \( \frac{3}{x+2} - \frac{4}{x-5} = \frac{2}{x^2-3x-10} \).

**Solution**

Factor all denominators.

$$\frac{3}{x+2} - \frac{4}{x-5} = \frac{2}{(x+2)(x-5)}$$

Find the lowest common denominator.

$$\text{LCD} = (x+2)(x-5)$$

Multiply all terms in the equation by the LCD.

$$(x+2)(x-5) \cdot \frac{3}{x+2} - (x+2)(x-5) \cdot \frac{4}{x-5} = (x+2)(x-5) \cdot \frac{2}{(x+2)(x-5)}$$

Divide out the common terms.

$$\frac{(x+2)^2}{(x-5)} \cdot \frac{3}{x+2} - \frac{(x+2)(x-5)^2}{x-5} \cdot \frac{4}{x-5} = \frac{(x+2)^2}{(x-5)} \cdot \frac{2}{(x+2)^2} \cdot (x-5)$$

The equation simplifies to

$$3(x-5) - 4(x+2) = 2$$

Simplify.

$$3x - 15 - 4x - 8 = 2$$

$$x = -25 \text{ Answer}$$
Check.

\[
\frac{3}{x+2} - \frac{4}{x-5} = \frac{3}{-25+2} - \frac{4}{-25-5} \approx 0.003
\]

\[
\frac{2}{x^2 - 3x - 10} = \frac{2}{(-25)^2 - 3(-25) - 10} \approx 0.003
\]

The answer checks out.

**Example 5**

Solve \(\frac{2x}{2x+1} + \frac{x}{x+4} = 1\).

**Solution**

Find the lowest common denominator.

\[
\text{LCD} = (2x + 1)(x + 4)
\]

Multiply all terms in the equation by the LCD.

\[
(2x + 1)(x + 4) \cdot \frac{2x}{2x + 1} + (2x + 1)(x + 4) \cdot \frac{x}{x + 4} = (2x + 1)(x + 4)
\]

Cancel all common terms.

\[
(2x + 1)^2 \cdot \frac{2x}{2x + 1} + (2x + 1)(x + 4)^2 \cdot \frac{x}{x + 4} = (2x + 1)(x + 4)
\]

The simplified equation is

\[
2x(x + 4) + x(2x + 1) = (2x + 1)(x + 4)
\]

Eliminate parentheses.

\[
2x^2 + 8x + 2x^2 + x = 2x^2 + 9x + 4
\]

Collect like terms.

\[
2x^2 = 4
\]

\[
x^2 = 2 \Rightarrow x = \pm \sqrt{2} \text{ Answer}
\]

Check.

\[
\frac{2x}{2x + 1} + \frac{x}{x + 4} = \frac{2\sqrt{2}}{2\sqrt{2} + 1} + \frac{\sqrt{2}}{\sqrt{2} + 4} \approx 0.739 + 0.261 = 1. \text{ The answer checks out.}
\]

\[
\frac{2x}{2x + 1} + \frac{x}{x + 4} = \frac{2(-\sqrt{2})}{2(-\sqrt{2}) + 1} + \frac{-\sqrt{2}}{-\sqrt{2} + 4} \approx 1.547 - 0.547 = 1. \text{ The answer checks out.}
\]
Solve Real-World Problems Using Rational Equations

Motion Problems
A motion problem with no acceleration is described by the formula distance = speed × time.
These problems can involve the addition and subtraction of rational expressions.

Example 6
Last weekend Nadia went canoeing on the Snake River. The current of the river is three miles per hour. It took Nadia the same amount of time to travel 12 miles downstream as three miles upstream. Determine the speed at which Nadia's canoe would travel in still water.

Solution
1. Define variables
Let $s =$ speed of the canoe in still water
Then, $s + 3 =$ the speed of the canoe traveling downstream
$s - 3 =$ the speed of the canoe traveling upstream

2. Construct a table.
We make a table that displays the information we have in a clear manner:

<table>
<thead>
<tr>
<th>Direction</th>
<th>Distance (miles)</th>
<th>Rate</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Downstream</td>
<td>12</td>
<td>$s + 3$</td>
<td>$t$</td>
</tr>
<tr>
<td>Upstream</td>
<td>3</td>
<td>$s - 3$</td>
<td>$t$</td>
</tr>
</tbody>
</table>

3. Write an equation.
Since distance = rate × time, we can say that: time = \[\frac{\text{distance}}{\text{rate}}\].
The time to go downstream is

$$t = \frac{12}{s + 3}$$

The time to go upstream is

$$t = \frac{3}{s - 3}$$

Since the time it takes to go upstream and downstream are the same then:

$$\frac{3}{s - 3} = \frac{12}{s + 3}$$

4. Solve the equation
Cross-multiply.

$$3(s + 3) = 12(s - 3)$$

Simplify.
3s + 9 = 12s - 36

Solve.

\[ s = 5 \text{ mi/hr} \] Answer

Nadia would travel 5 mi/hr or 5 mph in still water.

5. Check

Downstream: \( t = \frac{12}{5+3} = \frac{12}{8} = 1\frac{1}{2} \text{ hour} \); Upstream: \( t = \frac{3}{5-3} = \frac{3}{2} = 1\frac{1}{2} \text{ hour} \). The answer checks out.

Example 8

Peter rides his bicycle. When he pedals uphill he averages a speed of eight miles per hour, when he pedals downhill he averages 14 miles per hour. If the total distance he travels is 40 miles and the total time he rides is four hours, how long did he ride at each speed?

Solution

1. Define variables.

Let \( t_1 = \) time Peter bikes uphill, \( t_2 = \) time Peter bikes downhill, and \( d = \) distance he rides uphill.

2. Construct a table

We make a table that displays the information we have in a clear manner:

<table>
<thead>
<tr>
<th>Direction</th>
<th>Distance (miles)</th>
<th>Rate (mph)</th>
<th>Time (hours)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uphill</td>
<td>( d )</td>
<td>8</td>
<td>( t_1 )</td>
</tr>
<tr>
<td>Downhill</td>
<td>( 40 - d )</td>
<td>14</td>
<td>( t_2 )</td>
</tr>
</tbody>
</table>

3. Write an equation

We know that

\[
\text{time} = \frac{\text{distance}}{\text{rate}}
\]

The time to go uphill is

\[ t_1 = \frac{d}{8} \]

The time to go downhill is

\[ t_2 = \frac{40 - d}{14} \]

We also know that the total time is 4 hours.
2.7. Solutions of Rational Equations.

\[
\frac{d}{8} + \frac{40-d}{14} = 4
\]

4. Solve the equation.

Find the lowest common denominator:

\[
\text{LCD} = 56
\]

Multiply all terms by the common denominator:

\[
56 \cdot \frac{d}{8} + 56 \cdot \frac{40-d}{14} = 4 \cdot 56
\]

\[
7d + 160 - 4d = 224
\]

\[
3d = 64
\]

Solve.

\[
d \approx 21.3 \text{ miles Answer}
\]

5. Check.

Uphill: \( t = \frac{21.33}{8} \approx 2.67 \text{ hours} \); Downhill: \( t = \frac{40 - 21.33}{14} \approx 1.33 \text{ hours} \). The answer checks out.

Shares

Example 8

A group of friends decided to pool together and buy a birthday gift that cost $200. Later 12 of the friends decided not to participate any more. This meant that each person paid $15 more than the original share. How many people were in the group to start?

Solution

1. Define variables.

Let \( x \) = the number of friends in the original group

2. Make a table.

We make a table that displays the information we have in a clear manner:

<table>
<thead>
<tr>
<th></th>
<th>Number of People</th>
<th>Gift Price</th>
<th>Share Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Original group</td>
<td>( x )</td>
<td>200</td>
<td>( \frac{200}{x} )</td>
</tr>
<tr>
<td>Later group</td>
<td>( x - 12 )</td>
<td>200</td>
<td>( \frac{200}{x-12} )</td>
</tr>
</tbody>
</table>

3. Write an equation.

Since each persons share went up by $15 after 12 people refused to pay, we write the equation:
\[
\frac{200}{x - 12} = \frac{200}{x} + 15
\]

4. Solve the equation.

Find the lowest common denominator.

\[\text{LCD} = x(x - 12)\]

Multiply all terms by the LCM.

\[x(x - 12) \cdot \frac{200}{x - 12} = x(x - 12) \cdot \frac{200}{x} + x(x - 12) \cdot 15\]

Divide out common factors in each term:

\[x(x - 12)^{\frac{0}{1}} \cdot \frac{200}{x - 12} = x^1(x - 12) \cdot \frac{200}{x} + x(x - 12) \cdot 15\]

Simplify.

\[200x = 200(x - 12) + 15x(x - 12)\]

Eliminate parentheses.

\[200x = 200x - 2400 + 15x^2 - 180x\]

Collect all terms on one side of the equation.

\[0 = 15x^2 - 180x - 2400\]

Divide all terms by 15.

\[0 = x^2 - 12x - 160\]

Factor.

\[0 = (x - 20)(x + 8)\]

Solve.
The answer is $x = 20$ people. We discard the negative solution since it does not make sense in the context of this problem.

5. Check.

Originally $200$ shared among $20$ people is $10$ each. After $12$ people leave, $200$ shared among $8$ people is $25$ each. So each person pays $15$ more.

The answer checks out.
Chapter 3

Radical Functions

Chapter Outline

3.1 Graphs of Square Root Functions
3.2 Radical Expressions I
3.3 Radical Expressions II
3.4 Radical Equations
3.5 Imaginary and Complex Numbers
3.1 Graphs of Square Root Functions

Learning Objectives

- Graph and compare square root functions.
- Shift graphs of square root functions.
- Graph square root functions using a graphing calculator.
- Solve real-world problems using square root functions.

Introduction

In this chapter, you will be learning about a different kind of function called the square root function. You have seen that taking the square root is very useful in solving quadratic equations. For example, to solve the equation $x^2 = 25$ we take the square root of both sides $\sqrt{x^2} = \pm \sqrt{25}$ and obtain $x = \pm 5$. A square root function has the form $y = \sqrt{f(x)}$. In this type of function, the expression in terms of $x$ is found inside the square root symbol (also called the “radical” symbol).

Graph and Compare Square Root Functions

The square root function is the first time where you will have to consider the domain of the function before graphing. The domain is very important because the function is undefined if the expression inside the square root symbol is negative, and as a result there will be no graph in that region. In other words, since $\sqrt{-3}$ is not a real number, it cannot be graphed on the coordinate plane.

In order to cover how the graphs of the square root function behave, we should make a table of values and plot the points.

Example 1

Graph the function $f(x) = \sqrt{x}$.

Solution

Before we make a table of values, we need to find the domain of this square root function. The domain is found by realizing that the function is only defined when the expression inside the radical is greater than or equal to zero. We find that the domain is all values of $x$ such that $x \geq 0$.

This means that when we make our table of values, we must pick values of $x$ that are greater than or equal to zero. It is very useful to include the value of zero as the first value in the table and include many values greater than zero. This will help us in determining what the shape of the curve will be. It is often helpful to replace $f(x)$ with $y$ to complete the table of values.

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
<th>$(x,y)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$\sqrt{0} = 0$</td>
<td>$(0,0)$</td>
</tr>
</tbody>
</table>
After plotting the points \((x, y)\) generated in the table, the graph of \(f(x) = \sqrt{x}\) is pictured below.

The graphs of square root functions are always curved. The curve above is similar to a half of a parabola lying on its side. In fact, the square root function we graphed above comes from the equation \(y^2 = x\).

This is in the form of a parabola but with the \(x\) and \(y\) interchanged. We see that when we solve this expression for \(y\) we obtain two solutions \(y = \sqrt{x}\) and \(y = -\sqrt{x}\). The graph above shows the positive square root of this solution.

**Example 2**

*Graph the function* \(f(x) = -\sqrt{x}\).
### Solution

Once again, we must look at the domain of the function first. We see that the function is defined only for $x \geq 0$. Let’s make a table of values and calculate a few values of the function.

**Table 3.2:**

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
<th>$(x,y)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$-\sqrt{0} = 0$</td>
<td>$(0,0)$</td>
</tr>
<tr>
<td>1</td>
<td>$-\sqrt{1} = -1$</td>
<td>$(1,-1)$</td>
</tr>
<tr>
<td>2</td>
<td>$-\sqrt{2} \approx -1.4$</td>
<td>$(2,-1.4)$</td>
</tr>
<tr>
<td>3</td>
<td>$-\sqrt{3} \approx -1.7$</td>
<td>$(3,-1.7)$</td>
</tr>
<tr>
<td>4</td>
<td>$-\sqrt{4} = -2$</td>
<td>$(4,-2)$</td>
</tr>
<tr>
<td>5</td>
<td>$-\sqrt{5} \approx -2.2$</td>
<td>$(5,-2.2)$</td>
</tr>
<tr>
<td>6</td>
<td>$-\sqrt{6} \approx -2.4$</td>
<td>$(6,-2.4)$</td>
</tr>
<tr>
<td>7</td>
<td>$-\sqrt{7} \approx -2.6$</td>
<td>$(7,-2.6)$</td>
</tr>
<tr>
<td>8</td>
<td>$-\sqrt{8} \approx -2.8$</td>
<td>$(8,-2.8)$</td>
</tr>
<tr>
<td>9</td>
<td>$-\sqrt{9} = -3$</td>
<td>$(9,-3)$</td>
</tr>
</tbody>
</table>

The graph of $f(x) = -\sqrt{x}$ is pictured below.
Notice that if we graph the two separate functions on the same coordinate axes, the combined graph is a parabola lying on its side.

Now let’s compare square root functions that are multiples of each other.

**Example 3**

*Graph the following functions on the same coordinate plane.*

\[
\begin{align*}
  f(x) &= \sqrt{x} \\
  f(x) &= 2\sqrt{x} \\
  f(x) &= 3\sqrt{x} \\
  f(x) &= 4\sqrt{x}
\end{align*}
\]

**Solution**

*Here we will show just the graph without the table of values.*
### 3.1. Graphs of Square Root Functions

If we multiply the function by a constant greater than one, the function values (y-coordinates) increase faster. We can say the graph of the basic function is vertically stretched by 2, 3, 4, and so on.

We can say the 2, 3, and 4 outside of the square root vertically stretch the graph of \( f(x) = \sqrt{x} \) by 2, 3, and 4.

**Example 4**

*Graph the following functions on the same coordinate plane.*

\[
a. f(x) = \sqrt{x} \\
b. f(x) = \sqrt{2x} \\
c. f(x) = \sqrt{3x} \\
d. f(x) = \sqrt{4x}
\]

**Solution**

Notice that multiplying the expression inside the square root by a constant greater than one has the same effect as in the previous example but the function values increase at a slower rate because the entire function is effectively multiplied by the square root of the constant. Also note that the graph of \( f(x) = \sqrt{4x} \) is the same as the graph of \( f(x) = 2\sqrt{x} \). This makes sense algebraically since \( \sqrt{4x} = \sqrt{4 \cdot \sqrt{x}} = 2\sqrt{x} \).

Another way to think of the function \( f(x) = \sqrt{2x} \) is that input values (x-values) of half the value of the input (x-values) of \( f(x) = \sqrt{x} \) will produce the same outputs. For example, let’s consider the input or x-value of 4 for the function \( f(x) = \sqrt{x} \). \( f(4) = \sqrt{4} = 2 \). Now for the function \( f(x) = \sqrt{2x} \), let’s consider the input or x-value of 2, which is \( \frac{1}{2} \) of 4. \( f(2) = \sqrt{2 \cdot 2} = 2 \).

We can say that the factors of 2, 3, or 4 under the square root horizontally compress the graph of the function \( f(x) = \sqrt{x} \) by 2, 3,

We can say the factors of 2, 3, and 4 under the square root horizontally compress the graph of \( f(x) = \sqrt{x} \) by 2, 3, and 4.
Example 5
Graph the following functions on the same coordinate plane.

\[
\begin{align*}
 f(x) &= \sqrt{x} \\
 f(x) &= \frac{1}{2} \sqrt{x} \\
 f(x) &= \frac{1}{3} \sqrt{x} \\
 f(x) &= \frac{1}{4} \sqrt{x}
\end{align*}
\]

Solution

If we multiply the function by a constant between 0 and 1, the function values increase at a slower rate for smaller positive constants. The constant is often in fraction form.

We can say the \(\frac{1}{2}, \frac{1}{3}, \text{ and } \frac{1}{4}\) vertically compress the function \(f(x) = \sqrt{x}\).

Example 6

Graph the following functions on the same coordinate plane.

\[
\begin{align*}
 f(x) &= 2 \sqrt{x} \\
 f(x) &= -2 \sqrt{x}
\end{align*}
\]

Solution

If we multiply the function by a negative integer, the square root function is reflected across the \(x\)-axis.
Example 7

Graph the following functions on the same coordinate plane.

\[ f(x) = \sqrt{x} \]
\[ f(x) = \sqrt{-x} \]

Solution

Notice that for function \( f(x) = \sqrt{x} \) the domain is values of \( x \geq 0 \), and for function \( f(x) = \sqrt{-x} \) the domain is values of \( x \leq 0 \).

When we replace \( x \) with \( -x \) in a function, the graph is reflected about the \( y \)-axis.

Shift Graphs of Square Root Functions

Now, let’s see what happens to the square root function as we add positive and negative constants to the function.

Example 8

Graph the functions on the same coordinate plane.

\[ f(x) = \sqrt{x} \]
\[ f(x) = \sqrt{x} + 2 \]
\[ f(x) = \sqrt{x} - 2 \]
Solution

We see that the graph keeps the same shape, but is shifted up for adding positive constants and shifted down for adding negative constants or subtracting a positive constant.

**Example 9**

*Graph the functions on the same coordinate plane.*

\[
 f(x) = \sqrt{x} \\
 f(x) = \sqrt{x - 2} \\
 f(x) = \sqrt{x + 2}
\]

Solution

When we replace \( x \) with \((x \pm c)\), where \( c \) is a constant, the graph of the function shifts to the left for a positive constant and to the right for a negative constant because the domain shifts. Remember, there can’t be a negative number inside the square root symbol.

Notice \( f(x) = \sqrt{x + 2} \) shifts the graph of \( f(x) = \sqrt{x} \) 2 units left and \( f(x) = \sqrt{x - 2} \) shifts the graph of \( f(x) = \sqrt{x} \) 2 units right.

**Graph Square Root Functions Using a Graphing Calculator**

Next, we will demonstrate how to use the graphing calculator to plot square root functions.
Example 10

Graph the following functions using a graphing calculator:

a) \( f(x) = \sqrt{x+5} \)

b) \( f(x) = \sqrt{9-x^2} \)

Solution:

In all the cases we start by pressing the \([Y =]\) button and entering the function on the \([Y_1 =]\) of the screen.

We then press \([GRAPH]\) to display the results. Make sure your window is set appropriately in order to view the graph. This is done by pressing the \([WINDOW]\) button and choosing appropriate values for the Xmin, Xmax, Ymin and Ymax for the best graph view.

a)

The window of this graph is \(-6 \leq x \leq 6; -5 \leq y \leq 5\).

The domain of the function is \(x \geq -5\)

b)

The window of this graph is \(-5 \leq x \leq 5; -5 \leq y \leq 5\).

The domain of the function is \(-3 \leq x \leq 3\)
Mathematicians and physicists have studied the motion of a pendulum in great detail because this motion explains many other behaviors that occur in nature. This type of motion is called simple harmonic motion and it is very important because it describes anything that repeats periodically. Galileo was the first person to study the motion of a pendulum around the year 1600. He found that the time it takes a pendulum to complete a swing from a starting point back to the beginning does not depend on its mass or on its angle of swing (as long as the angle of the swing is small). Rather, it depends only on the length of the pendulum.

The time it takes a pendulum to swing from a starting point and back to the beginning is called the period of the pendulum.
Galileo found that the period \( T \) of a pendulum is proportional to the square root of its length \( L \). \( T = a \sqrt{L} \). The proportionality constant depends on the acceleration of gravity \( a = \frac{2\pi}{\sqrt{g}} \). At sea level on Earth the acceleration of gravity is \( g = 9.81 \text{ m/s}^2 \) (meters per second squared). Using this value of gravity, we find \( a = 2.0 \) with units of \( \text{s/}\sqrt{\text{m}} \) (seconds divided by the square root of meters). Up until the mid 20th century, all clocks used pendulums as their central time keeping component.

Example 11

*Graph the period of a pendulum of a clock swinging in a house on Earth at sea level as we change the length of the pendulum. What does the length of the pendulum need to be for its period to be one second?*

**Solution**

The function for the period of a pendulum at sea level is: \( T = 2 \sqrt{L} \).

We make a graph with the horizontal axis representing the length \( L \) of the pendulum and with the vertical axis representing the period \( T \) of the pendulum.

We start by making a table of values.

<table>
<thead>
<tr>
<th>( L )</th>
<th>( T )</th>
<th>( (L, T) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>( T = 2 \sqrt{0} = 0 )</td>
<td>( (0, 0) )</td>
</tr>
<tr>
<td>1</td>
<td>( T = 2 \sqrt{1} \approx 2.8 )</td>
<td>( (1, 2.8) )</td>
</tr>
<tr>
<td>2</td>
<td>( T = 2 \sqrt{2} = 2 )</td>
<td>( (2, 2) )</td>
</tr>
<tr>
<td>3</td>
<td>( T = 2 \sqrt{3} \approx 3.5 )</td>
<td>( (3, 3.5) )</td>
</tr>
<tr>
<td>4</td>
<td>( T = 2 \sqrt{4} = 4 )</td>
<td>( (4, 4) )</td>
</tr>
</tbody>
</table>
TABLE 3.3: (continued)

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>$T = 2 \sqrt{5} \approx 4.5$</td>
<td>(5, 4.5)</td>
</tr>
</tbody>
</table>

Now let’s graph the function.

![Graph of the function](image)

We can see from the graph that a length of approximately $\frac{4}{3}$ meters gives a period of one second. We can confirm this answer by using our function for the period and plugging in $T = 1$ second.

$$T = 2 \sqrt{L} \Rightarrow 1 = 2 \sqrt{L}$$

Square both sides of the equation:

$$1 = 4L$$

Solve for $L$:

$$L = \frac{1}{4} \text{ meters}$$

Example 12

“Square” TV screens have an aspect ratio of 4:3. This means that for every four inches of length on the horizontal, there are three inches of length on the vertical. TV sizes represent the length of the diagonal of the television screen. Graph the length of the diagonal of a screen as a function of the area of the screen. What is the diagonal of a screen with an area of 180 in$^2$?

Solution

![Diagram of triangle with sides $\frac{3}{4}x$, $x$, and $d$]

Let $d =$ length of the diagonal, $x =$ horizontal length
4 \cdot \text{vertical length} = 3 \cdot \text{horizontal length}

Or,

\text{vertical length} = \frac{3}{4}x.

The area of the screen is: \( A = \text{length} \cdot \text{width} \) or \( A = \frac{3}{4}x^2 \)

Find how the diagonal length and the horizontal length are related by using the Pythagorean theorem, \( a^2 + b^2 = c^2 \).

\[
x^2 + \left(\frac{3}{4}x\right)^2 = d^2
\]

\[
x^2 + \frac{9}{16}x^2 = d^2
\]

\[
\frac{25}{16}x^2 = d^2 \Rightarrow x^2 = \frac{16}{25}d^2 \Rightarrow x = \frac{4}{5}d
\]

\[
A = \frac{3}{4} \left(\frac{4}{5}d\right)^2 = \frac{3}{4} \cdot \frac{16}{25}d^2 = \frac{12}{25}d^2
\]

We can also find the diagonal length as a function of the area \( \frac{25}{16}A \) or \( d = \frac{5}{2 \sqrt{3}} \sqrt{A} \).

Make a graph where the horizontal axis represents the area \( A \) of the television screen and the vertical axis is the length of the diagonal \( d \). Let’s make a table of values.
From the graph we can estimate that when the area of a TV screen is 180 in\(^2\) the length of the diagonal is approximately 19.5 inches. We can confirm this by substituting \(a = 180\) into the formula that relates the diagonal to the area.

\[
d = \frac{5}{2\sqrt{3}} \sqrt{A} = \frac{5}{2\sqrt{3}} \sqrt{180} = 19.4 \text{ inches}
\]
Learning objectives

- Use the product and quotient properties of radicals to simplify radicals.
- Add and subtract radical expressions.
- Solve real-world problems using square root functions.

Introduction

A radical reverses the operation of raising a number to a power. For example, to find the square of 4 we write

\[ 4^2 = 4 \cdot 4 = 16. \]

The reverse process is called finding the square root. The symbol for a square root is \( \sqrt{} \). This symbol is also called the **radical**. When we take the square root of a number, the result is a number which when squared gives the number under the square root. For example,

\[ \sqrt{9} = 3 \quad \text{since} \quad 3^2 = 3 \cdot 3 = 9 \]

The index of a radical indicates which root of the number we are seeking. Square roots have an index of 2 but most times this index is not written.

\[ \sqrt{36} = \sqrt[2]{36} = 6 \quad \text{since} \quad 6^2 = 36 \]

The cube root of a number gives a number which when raised to the third power gives the number under the radical.

\[ \sqrt[3]{64} = 4 \quad \text{since} \quad 4^3 = 4 \cdot 4 \cdot 4 = 64 \]

The fourth root of number gives a number which when raised to the power four gives the number under the radical sign.

\[ \sqrt[4]{81} = 3 \quad \text{since} \quad 3^4 = 3 \cdot 3 \cdot 3 \cdot 3 = 81 \]

The index is 4 and the 81 is called the **radicand**.

**Even and odd roots**

Radical expressions that have even indices are called **even roots** and radical expressions that have odd indices are called **odd roots**. There is a very important difference between even and odd roots in that they give drastically different results when the number inside the radical sign is negative.

Any real number raised to an even power results in a positive number. Therefore, when the index of a radical is even, the number inside the radical sign must be non-negative in order to get a real number answer.
On the other hand, a positive number raised to an odd power is positive and a negative number raised to an odd power is negative. Thus, a negative number inside the radical with an odd index is not a problem. It results in a negative number.

**Example 1**

_Evaluate each radical expression._

a) \(\sqrt{121}\)

b) \(\sqrt[3]{125}\)

c) \(\sqrt[4]{-625}\)

d) \(\sqrt[5]{-32}\)

**Solution**

a) \(\sqrt{121} = 11\)

b) \(\sqrt[3]{125} = 5\)

c) \(\sqrt[4]{-625}\) is not a real number

d) \(\sqrt[5]{-32} = -2\)

**Use the Product and Quotient Properties of Radicals**

Radicals can be rewritten as exponents with rational powers. The radical \(y = \sqrt[n]{an}\) is defined as \(a^{\frac{n}{n}}\).

**Example 2**

_Write each expression as an exponent with a rational value for the exponent._

a) \(\sqrt{5}\)

b) \(\sqrt{a}\)

c) \(\sqrt[4]{4xy}\)

d) \(\sqrt[6]{x^5}\)

**Solution**

a) \(\sqrt{5} = 5^{\frac{1}{2}}\)

b) \(\sqrt{a} = a^{\frac{1}{2}}\)

c) \(\sqrt[4]{4xy} = (4xy)^{\frac{1}{4}}\)

d) \(\sqrt[6]{x^5} = x^{\frac{5}{6}}\)

As a result of this property, for any non-negative number \(\sqrt[n]{an} = a^{\frac{n}{n}} = a^{1} = a\).

Since roots of numbers can be treated as powers, we can use exponent rules to simplify and evaluate radical expressions. Let’s review the product and quotient rule of exponents.

\[
\begin{align*}
\text{Raising a product to a power} & \quad (x \cdot y)^n = x^n \cdot y^n \\
\text{Raising a quotient to a power} & \quad \left(\frac{x}{y}\right)^n = \frac{x^n}{y^n}
\end{align*}
\]

In radical notation, these properties are written as
3.2. Radical Expressions I

Raising a product to a power
\[ \sqrt{x \cdot y} = \sqrt{x} \cdot \sqrt{y} \]

Raising a quotient to a power
\[ \sqrt{\frac{x}{y}} = \frac{\sqrt{x}}{\sqrt{y}} \]

A very important application of these rules is reducing a radical expression to its simplest form. This means that we apply the root on all the factors of the number that are perfect roots and leave all factors that are not perfect roots inside the radical sign.

For example, in the expression \( \sqrt{16} \), the number is a perfect square because \( 16 = 4^2 \). This means that we can simplify.

\[ \sqrt{16} = \sqrt{4^2} = 4 \]

Thus, the square root disappears completely. This happens when the index and exponent are the same.

On the other hand, in the expression, the number \( \sqrt{32} \) is not a perfect square so we cannot remove the square root. However, we notice that \( 32 = 16 \cdot 2 \), so we can write 32 as the product of a perfect square and another number.

\[ \sqrt{32} = \sqrt{16 \cdot 2} = \sqrt{16} \cdot \sqrt{2} \]

If we apply the “raising a product to a power” rule we obtain

\[ \sqrt{32} = \sqrt{16} \cdot \sqrt{2} = 4 \cdot \sqrt{2} = 4 \sqrt{2} \]

Example 3

Write the following expression in the simplest radical form.

a) \( \sqrt{8} \)
b) \( \sqrt{50} \)
c) \( \sqrt{\frac{125}{36}} \)

Solution

The strategy is to write the number under the square root as the product of a perfect square and another number. The goal is to find the highest perfect square possible, however, if we don’t we can repeat the procedure until we cannot simplify any longer.

a) We can write \( 8 = 4 \cdot 2 \) so \( \sqrt{8} = \sqrt{4 \cdot 2} \)

Use the rule for raising a product to a power \( \sqrt{4 \cdot 2} = \sqrt{4} \cdot \sqrt{2} = 2 \sqrt{2} \)

b) We can write \( 50 = 25 \cdot 2 \) so \( \sqrt{50} = \sqrt{25 \cdot 2} \)

Use the rule for raising a product to a power \( \sqrt{25 \cdot 2} = 5 \sqrt{2} \)

c) Use the rule for raising a quotient to a power to separate the fraction.

\[ \sqrt{\frac{125}{36}} = \frac{\sqrt{125}}{\sqrt{36}} \]
Rewrite each radical as a product of a perfect square and another number.

\[
\frac{\sqrt{25 \cdot 5}}{\sqrt{6 \cdot 6}} = \frac{5 \sqrt{5}}{6}
\]

In algebra, when simplifying quotients with radical, we often don’t want a radical in the denominator. The process eliminating a radical from the denominator is often called rationalizing the denominator. We will see this process in the next set of examples.

The same method can be applied to reduce radicals of different indices to their simplest form.

**Example 4**

Write the following expression in the simplest radical form.

a) \(\sqrt[3]{40}\)

b) \(\sqrt{\frac{125}{27}}\)

c) \(\sqrt[3]{135}\)

**Solution**

In these cases we look for the highest possible perfect cube, fourth power, etc. as indicated by the index of the radical.

a) Here we are looking for the product of the highest perfect cube and another number. We write

\[
\sqrt[3]{40} = \sqrt[3]{8 \cdot 5} = \sqrt[3]{2^3 \cdot 5} = 2 \sqrt[3]{5}
\]

b) Here we are looking for the product of the highest perfect fourth power and another number. Rewrite as the quotient of two radicals

\[
\sqrt[4]{\frac{125}{27}} = \frac{\sqrt[4]{125}}{\sqrt[4]{27}}
\]

Simplify each radical separately

\[
= \frac{\sqrt{25 \cdot 5}}{\sqrt{9 \cdot 3}} = \frac{5 \sqrt{5}}{3 \sqrt{3}} = \frac{5 \sqrt{5} \cdot \sqrt{3}}{3 \sqrt{3} \cdot \sqrt{3}} = \frac{5 \sqrt{15}}{9}
\]

Eliminate the radical from the denominator

\[
= \frac{5 \sqrt{5}}{3 \sqrt{3}} \cdot \frac{\sqrt{3}}{\sqrt{3}} = \frac{5 \sqrt{15}}{9}
\]

c) Here we are looking for the product of the highest perfect cube root and another number. Often it is not very easy to identify the perfect root in the expression under the radical sign.

In this case, we can factor the number under the radical sign completely by using a factor tree.
We see that $135 = 3 \cdot 3 \cdot 5 = 3^3 \cdot 5$

Therefore $\sqrt[3]{135} = \sqrt[3]{3^3 \cdot 5} = \sqrt[3]{3^3} \cdot \sqrt[3]{5} = 3 \sqrt[3]{5}$

Here are some examples involving variables.

**Example 5**

Write the following expression in the simplest radical form.

a) $\sqrt[3]{12x^3y^5}$

b) $\sqrt[4]{\frac{1250x^7}{405y^9}}$

**Solution**

Treat constants and each variable separately and write each expression as the products of a perfect power as indicated by the index of the radical and another number.

a) Rewrite as a product of radicals.

$\sqrt[3]{12x^3y^5} = \sqrt[3]{12} \cdot \sqrt[3]{x^3} \cdot \sqrt[3]{y^5}$

Simplify each radical separately.

$(\sqrt[3]{4} \cdot 3) \cdot (\sqrt[3]{x^2} \cdot x) \cdot (\sqrt[3]{y^4} \cdot y) = (2 \sqrt[3]{3}) \cdot (x \sqrt[3]{x}) \cdot (y^2 \sqrt[3]{y})$

Combine all factors outside and inside the radical sign.

$= 2xy^2 \sqrt[3]{3xy}$

b) Rewrite as a quotient of radicals.

$\sqrt[4]{\frac{1250x^7}{405y^9}} = \frac{\sqrt[4]{1250x^7}}{\sqrt[4]{405y^9}}$

Simplify each radical separately.

$= \frac{\sqrt[4]{625 \cdot 2} \cdot \sqrt[4]{x^4} \cdot x}{\sqrt[4]{81} \cdot 3 \sqrt[4]{y^4} \cdot y} = \frac{5 \sqrt[4]{2} \cdot x \cdot x}{3 \sqrt[4]{5} \cdot y \cdot y}$

$= \frac{5x \sqrt[4]{2x^3}}{3y^2 \sqrt[4]{5y}} \cdot \frac{\sqrt[4]{5} \cdot 5 \cdot 5 \cdot y \cdot y \cdot y \cdot y \cdot y \cdot y \cdot y}{\sqrt[4]{5} \cdot 5 \cdot 5 \cdot 5 \cdot y \cdot y \cdot y \cdot y \cdot y \cdot y \cdot y} = \frac{5x \sqrt[4]{250x^3y^3}}{15y^3} = \frac{x \sqrt[4]{250x^3y^3}}{3y^3}$
Add and Subtract Radical Expressions

When we add and subtract radical expressions, we can combine radical terms only when they have the same index and the same expression under the radical sign. This is a similar procedure to combining like terms in variable expressions. For example,

\[ 4 \sqrt{2} + 5 \sqrt{2} = 9 \sqrt{2} \]

or

\[ 2 \sqrt{3} - \sqrt{2} + 5 \sqrt{3} + 10 \sqrt{2} = 7 \sqrt{3} + 9 \sqrt{2} \]

It is important to simplify all radicals to their simplest form in order to make sure that we are combining all possible like terms in the expression. For example, the expression \( \sqrt{8} - 2 \sqrt{50} \) looks like it cannot be simplified any more because it has no like terms. However, when we write each radical in its simplest form we have

\[ \sqrt{8} = 2 \sqrt{2}, \quad 2 \sqrt{50} = 2 \cdot 5 \sqrt{2} = 10 \sqrt{2} \]

\[ \sqrt{8} - 2 \sqrt{50} = 2 \sqrt{2} - 10 \sqrt{2} = -8 \sqrt{2} \]

Notice how after simplify, we have like radicals because the index and radicand is the same.

Example 6

Simplify the following expressions as much as possible.

a) \( 4 \sqrt{3} + 2 \sqrt{12} \)

b) \( 10 \sqrt{24} - \sqrt{28} \)

Solution

a) Simplify \( \sqrt{12} \) to its simplest form. \( = 4 \sqrt{3} + 2 \cdot 2 \sqrt{3} = 4 \sqrt{3} + 4 \sqrt{3} = 8 \sqrt{3} \)

Combine like terms. \( = 8 \sqrt{3} \)

b) Simplify \( \sqrt{24} \) and \( \sqrt{28} \) to their simplest form. \( = 10 \sqrt{6} - \sqrt{7} \cdot 4 = 20 \sqrt{6} - 2 \sqrt{7} \)

There are no like terms.

Example 7

Simplify the following expressions as much as possible.

a) \( 4 \sqrt{128} - 3 \sqrt{250} \)

b) \( 3 \sqrt{x^3} - 4x \sqrt{9x} \)

Solution
3.2. Radical Expressions I

a) Rewrite radicals in simplest terms.
\[ 4\sqrt[3]{64} \cdot 2 - \sqrt[3]{125} \cdot 2 = 16\sqrt[3]{2} - 5\sqrt[3]{2} \]
Combine like terms. = \[11\sqrt[3]{2}\]

b) Rewrite radicals in simplest terms.
\[ 3\sqrt[3]{x^2 \cdot x} - 4x \sqrt[3]{9x} = 3x \sqrt[3]{x} - 12x \sqrt[3]{x} \]
Combine like terms. = \[-9x \sqrt[3]{x}\]

Solve Real-World Problems Using Radical Expressions

Radicals often arise in problems involving areas and volumes of geometrical figures.

Example 10

The volume of a soda can is 355 cm³. The height of the can is four times the radius of the base. Find the radius of the base of the cylinder.

Solution

1. Make a sketch.
2. Let \(x\) = the radius of the cylinder base
3. Write an equation.

The volume of a cylinder is given by

\[ V = \pi r^2 \cdot h \]

4. Solve the equation.

\[ 355 = \pi x^2 (4x) \]
\[ 355 = 4\pi x^3 \]
\[ x^3 = \frac{355}{4\pi} \]
\[ x = \sqrt[3]{\frac{355}{4\pi}} = 3.046 \text{ cm} \]
5. Check by substituting the result back into the formula.

\[ V = \pi r^2 \cdot h = \pi (3.046)^2 \cdot (4 \cdot 3.046) = 355 \text{ cm}^3 \]

So the volume is 355 cm$^3$.

The answer checks.
3.3 Radical Expressions II

Learning objectives

- Multiply radical expressions.
- Rationalize the denominator.

Multiply Radical Expressions.

When we multiply radical expressions, we use the “raising a product to a power” rule $\sqrt{x \cdot y} = \sqrt{x} \cdot \sqrt{y}$.

In this case we apply this rule in reverse. For example

$$\sqrt{6} \cdot \sqrt{8} = \sqrt{48}$$

Make sure that the answer is written in simplest radical form

$$\sqrt{48} = \sqrt{16 \cdot 3} = 4 \sqrt{3}$$

We will also make use of the fact that

$$\sqrt{a} \cdot \sqrt{a} = \sqrt{a^2} = a.$$ 

When we multiply expressions that have numbers on both the outside and inside the radical, we treat the numbers outside the radical and the numbers inside the radical separately.

For example

$$a \sqrt{b} \cdot c \sqrt{d} = ac \sqrt{bd}.$$ 

Example 1

Multiply the following expressions.

a) $\sqrt{2} \left( \sqrt{3} + \sqrt{5} \right)$

b) $\sqrt{5} \left( 5 \sqrt{3} - 2 \sqrt{5} \right)$

c) $2 \sqrt{x} \left( 3 \sqrt{y} - \sqrt{x} \right)$

Solution

In each case we use distribution to eliminate the parenthesis.

a)
Distribute $\sqrt{2}$ inside the parenthesis.

$\sqrt{2} \left( \sqrt{3} + \sqrt{5} \right) = \sqrt{2} \cdot \sqrt{3} + \sqrt{2} \cdot \sqrt{5}$

Use the raising a product to a power rule.

Simplify.

$= \sqrt{6} + \sqrt{10}$

b)

Distribute $\sqrt{5}$ inside the parenthesis.

$\sqrt{5} \left( 5 \sqrt{3} - 2 \sqrt{6} \right) = 5 \sqrt{15} - 2 \sqrt{30}$

Simplify.

$= 5 \sqrt{15} - 5 \sqrt{15} = 5 \sqrt{15} - 10$

c)

Distribute $2 \sqrt{x}$ inside the parenthesis.

$2 \sqrt{x} \left( 3 \sqrt{y} - \sqrt{x} \right) = (2 \cdot 3) \left( \sqrt{x} \cdot \sqrt{y} - \sqrt{x} \cdot \sqrt{x} \right)$

Multiply. $= 6 \sqrt{xy} - 2 \sqrt{x^2}$

Simplify. $= 6 \sqrt{xy} - 2x$

Example 2

Multiply the following expressions.

a) $\left( 2 + \sqrt{3} \right) \left( 2 - \sqrt{6} \right)$

b) $\left( 2 \sqrt{x} - 1 \right) \left( 5 - \sqrt{x} \right)$

Solution

In each case we use distribution to eliminate the parenthesis.

a)

Multiply. $\left( 2 + \sqrt{3} \right) \left( 2 - \sqrt{6} \right) = (2 \cdot 2) - (2 \cdot \sqrt{6}) + (2 \cdot \sqrt{3}) - (\sqrt{3} \cdot \sqrt{6})$

Simplify. $= 4 - 2 \sqrt{6} + 2 \sqrt{3} - 30$

b)

Distribute. $\left( 2 \sqrt{x} - 1 \right) \left( 5 - \sqrt{x} \right) = 10 \sqrt{x} - 2x - 5 + \sqrt{x}$

Simplify. $= 11 \sqrt{x} - 2x - 5$

Example 3

Simplify.

a) $\sqrt[3]{\sqrt{x}}$

b) $\sqrt[5]{\sqrt{x}}$

Solution

a) Write using rational exponents.
3.3. Radical Expressions II

\[
\sqrt[3]{\sqrt{x}} = (x^{\frac{1}{2}})^{\frac{1}{3}}
\]

Since we have a power to a power, we multiply the exponents. \((a^m)^n = a^{m \cdot n}\)

\[
\sqrt[3]{\sqrt{x}} = (x^{\frac{1}{2}})^{\frac{1}{3}} = x^{\frac{1}{6}}
\]

Now write in radical form.

\[x^{\frac{1}{6}} = \sqrt[6]{x}\]

b) Write using rational exponents.

\[
\sqrt[5]{\sqrt{x}} = (x^{\frac{1}{2}})^{\frac{1}{5}}
\]

Since we have a power to a power, we multiply the exponents. \((a^m)^n = a^{m \cdot n}\)

\[
\sqrt[5]{\sqrt{x}} = (x^{\frac{1}{2}})^{\frac{1}{5}} = x^{\frac{1}{10}}
\]

Now write in radical form.

\[x^{\frac{1}{10}} = \sqrt[10]{x}\]

Example 4

Multiply and simplify.
\[
\sqrt[3]{x} \cdot \sqrt[4]{x}
\]

Solution

Write using rational exponents.

\[
\sqrt[3]{x} \cdot \sqrt[4]{x} = x^{\frac{1}{3}} \cdot x^{\frac{1}{4}}
\]

Since we are multiplying and the bases are the same, we add the exponents. \((a^m) \cdot (a^n) = a^{m+n}\) Notice we have to obtain a common denominator for 1/3 and 1/4, which would be 12.

\[
x^{\frac{1}{3}} \cdot x^{\frac{1}{4}} = x^{\frac{4}{12}} \cdot x^{\frac{3}{12}} = x^{\frac{7}{12}}
\]

Now write in radical form.

\[x^{\frac{7}{12}} = \sqrt[12]{x^7}\]
Rationalize the Denominator

Often when we work with radicals, we end up with a radical expression in the denominator of a fraction. We can simplify such expressions even further by eliminating the radical expression from the denominator of the expression. This process is called rationalizing the denominator.

There are two cases we will examine.

Case 1 There is a single radical expression in the denominator \( \frac{2}{\sqrt{3}} \).

In this case, we multiply the numerator and denominator by a radical expression that makes the expression inside the radical into a perfect power. In the example above, we multiply by the \( \sqrt{3} \).

\[
\frac{2}{\sqrt{3}} \cdot \frac{\sqrt{3}}{\sqrt{3}} = \frac{2\sqrt{3}}{3}
\]

Next, let’s examine \( \frac{7}{\sqrt{3}} \).

In this case, we need to make the number inside the cube root a perfect cube. We need to multiply the numerator and the denominator by \( \frac{\sqrt[3]{25}}{\sqrt[3]{5}} \) since the index determines how many factors must be under the radical in the denominator to simplify perfectly or make a perfect nth root.

\[
\frac{7}{\sqrt[3]{5}} \cdot \frac{\sqrt[3]{25}}{\sqrt[3]{5}} = \frac{7\sqrt[3]{25}}{5}
\]

Case 2 The expression in the denominator is a radical expression that contains more than one term.

Consider the expression \( \frac{2}{2 + \sqrt{3}} \).

In order to eliminate the radical from the denominator, we multiply it by \( \left(2 - \sqrt{3}\right) \), which is the irrational conjugate of \( (2 + \sqrt{3}) \). This is a good choice because the product \( \left(2 + \sqrt{3}\right) \left(2 - \sqrt{3}\right) \) is a product of a sum and a difference which multiplies as follows.

\[
\left(2 + \sqrt{3}\right) \left(2 - \sqrt{3}\right) = 2^2 - \left(\sqrt{3}\right)^2 = 4 - 3 = 1
\]

We multiply the numerator and denominator by \( 2 - \sqrt{3} \) and get

\[
\frac{2}{2 + \sqrt{3}} \cdot \frac{2 - \sqrt{3}}{2 - \sqrt{3}} = \frac{2(2 - \sqrt{3})}{4 - 3} = \frac{4 - 2\sqrt{3}}{1}
\]

Now consider the expression \( \frac{\sqrt{x-1}}{\sqrt{x-2}\sqrt{y}} \).

In order to eliminate the radical expressions in the denominator, we must multiply by \( \sqrt{x+2\sqrt{y}} \).

We obtain
\[
\frac{\sqrt{x} - 1}{\sqrt{x} - 2 \sqrt{y}} \cdot \frac{\sqrt{x} + 2 \sqrt{y}}{\sqrt{x} + 2 \sqrt{y}} = \frac{(\sqrt{x} - 1)(\sqrt{x} + 2 \sqrt{y})}{(\sqrt{x} - 2 \sqrt{y})(\sqrt{x} + 2 \sqrt{y})}
\]
\[
= \frac{x + 2 \sqrt{xy} - \sqrt{x} - 2 \sqrt{y}}{4 - 4y}
\]
3.4 Radical Equations

Learning Objectives

- Solve a radical equation.
- Solve radical equations with radicals on both sides.
- Identify extraneous solutions.
- Solve real-world problems using square root functions.

Introduction

When the variable in an equation appears inside a radical, the equation is called a radical equation. The first steps in solving a radical equation are to perform operations that will eliminate the radical and change the equation into a polynomial equation. A common method for solving radical equations is to isolate the most complicated radical on one side of the equation and raise both sides of the equation to the power that will eliminate the radical and the power will be determined by the index. If there are any radicals left in the equation after simplifying, we can repeat this procedure until all radicals are gone. Once the equation is changed into a polynomial equation, we can solve it with the methods we already know.

We must be careful when we use this method, because whenever we raise an equation to a power, we could introduce false solutions that are not in fact solutions to the original problem. These are called extraneous solutions. In order to make sure we get the correct solutions, we must always check all solutions in the original radical equation.

Solve a Radical Equation

Let’s consider a few simple examples of radical equations where only one radical appears in the equation.

Example 1

Find the real solutions of the equation \(\sqrt{2x - 1} = 5\).

Solution

Since the radical expression is already isolated, we square both sides of the equation in order to eliminate the radical sign since the index of the square root is a 2.

\[
\left(\sqrt{2x - 1}\right)^2 = 5^2
\]

Remember that \( (\sqrt{a})^2 = a \) so the equation simplifies to

\[
2x - 1 = 25
\]

Add one to both sides.

\[
2x = 26
\]

Divide both sides by 2.

\[
x = 13
\]

Finally, we need to plug the solution in the original equation to see if it is a valid solution.

\[
\sqrt{2x - 1} = \sqrt{2(13) - 1} = \sqrt{26 - 1} = \sqrt{25} = 5
\]
The answer checks.

Example 2

*Find the real solutions of* \( \sqrt[3]{3 - 7x} - 3 = 0. \)

**Solution**

We isolate the radical on one side of the equation.

\[
\sqrt[3]{3 - 7x} = 3
\]

Raise each side of the equation to the third power since the index of the square root is a 2.

\[
\left( \sqrt[3]{3 - 7x} \right)^3 = 3^3
\]

Simplify.

\[
3 - 7x = 27
\]

Subtract 3 from each side.

\[
-7x = 24
\]

Divide both sides by -7.

\[
x = \frac{-24}{7}
\]

Check

\[
\sqrt[3]{3 - 7x} - 3 = \sqrt[3]{3 - 7 \left( -\frac{24}{7} \right)} - 3 = \sqrt[3]{3 + 24 - 3} = \sqrt[3]{27} - 3 = 3 - 3 = 0.
\]

The answer checks.

Example 3

*Find the real solutions of* \( \sqrt{10 - x^2} - x = 2. \)

**Solution**
We isolate the radical on one side of the equation.

\[ \sqrt{10 - x^2} = 2 + x \]

Square each side of the equation.

\[ (\sqrt{10 - x^2})^2 = (2 + x)^2 \]

Simplify.

\[ 10 - x^2 = 4 + 4x + x^2 \]

Move all terms to one side of the equation.

\[ 0 = 2x^2 + 4x - 6 \]

Factor out the GCF.

\[ 0 = 2(x^2 + 2x - 3) \]

Factor.

\[ 0 = 2(x + 3)(x - 1) \]

Use the Zero Product Property to solve.

\[ x = -3 \text{ or } x = 1 \]

Check

\[ \sqrt{10 - (-1)^2} - 1 = \sqrt{9} - 1 = 3 - 1 = 2 \]

The answer checks.

\[ \sqrt{10 - (-3)^2} - (-3) = \sqrt{1} + 3 = 1 + 3 = 4 \neq 2 \]

This solution does not check.

The equation has only one solution, \( x = 1 \). The solution \( x = -3 \) is called an extraneous solution.

**Solve Radical Equations with More than One Radical**

Often equations have more than one radical expression. The strategy in this case is to isolate the most complicated radical expression and raise the equation to the appropriate power determined by the index. We then repeat the process until all radical signs are eliminated.

**Example 4**

*Find the real roots of the equation* \( \sqrt{2x + 1} - \sqrt{x - 3} = 2. \)

**Solution**

Isolate one of the radical expressions

\[ \sqrt{2x + 1} = 2 + \sqrt{x - 3} \]

Square both sides

\[ (\sqrt{2x + 1})^2 = (2 + \sqrt{x - 3})^2 \]

Eliminate parentheses

\[ 2x + 1 = 4 + 4\sqrt{x - 3} + x - 3 \]
Simplify.

\[ x = 4 \sqrt{x - 3} \]

Square both sides of the equation.

\[ x^2 = (4 \sqrt{x - 3})^2 \]

Eliminate parentheses.

\[ x^2 = 16(x - 3) \]

Simplify.

\[ x^2 = 16x - 48 \]

Move all terms to one side of the equation.

\[ x^2 - 16x + 48 = 0 \]

Factor.

\[ (x - 12)(x - 4) = 0 \]

Solve.

\[ x = 12 \text{ or } x = 4 \]

Check

\[ \sqrt{2(12)+1} - \sqrt{12-3} = \sqrt{25} - \sqrt{9} = 5 - 3 = 2 \]

The solution checks out.

\[ \sqrt{2(4)+1} - \sqrt{4-3} = \sqrt{9} - \sqrt{1} = 3 - 1 = 2 \]

The solution checks out.

The equation has two solutions: \( x = 12 \) and \( x = 4 \).
Identify Extraneous Solutions to Radical Equations

We saw in Example 3 that some of the solutions that we find by solving radical equations do not check when we substitute (or “plug in”) those solutions back into the original radical equation. These are called extraneous solutions. It is very important to check the answers we obtain by plugging them back into the original equation. In this way, we can distinguish between the real and the extraneous solutions of an equation.

Example 5

Find the real roots of the equation \( \sqrt{x-3} - \sqrt{x} = 1 \).

Solution

Isolate one of the radical expressions.

\[ \sqrt{x-3} = \sqrt{x} + 1 \]

Square both sides.

\[ (\sqrt{x-3})^2 = (\sqrt{x} + 1)^2 \]

Remove parenthesis.

\[ x - 3 = (\sqrt{x})^2 + 2\sqrt{x} + 1 \]

Isolate the radical again.

\[ x - 3 = x + 2\sqrt{x} + 1 \]

Now isolate the remaining radical.

\[ -4 = 2\sqrt{x} \]

Divide all terms by 2.

\[ -2 = \sqrt{x} \]

Square both sides.

\[ x = 4 \]

Check

\[ \sqrt{4-3} - \sqrt{4} = \sqrt{1} - 2 = 1 - 2 = -1 \]

The solution does not check out.

The equation has no real solutions. Therefore, \( x = 4 \) is an extraneous solution.
Solve Real-World Problems using Radical Equations

Radical equations often appear in problems involving areas and volumes of objects.

Example 6

The area of Anita’s square vegetable garden is 21 square-feet larger that Fred’s square vegetable garden. Anita and Fred decide to pool their money together and buy the same kind of fencing for their gardens. If they need 84 feet of fencing, what is the size of their gardens?

Solution

1. Make a sketch
2. Define variables

Let Fred’s area be \( x \)
Anita’s area \( x + 21 \)

The area of a square is equal to the length of one side squares.

\[
A = s^2
\]

Therefore, if the area of a square is \( x \), it following the length of one side would be \( \sqrt{x} \).

From the given information, we can conclude the following:

Side length of Fred’s garden is \( \sqrt{x} \)
Side length of Anita’s garden is \( \sqrt{x + 21} \)

3. Find an equation

The amount of fencing is equal to the combined perimeters of the two squares. The perimeter of a square is equal to the length of the 4 equal sides.

\[
P = 4s
\]

Therefore Fred requires \( 4\sqrt{x} \) feet of fence and Anita requires \( 4\sqrt{x + 21} \) feet of fence. Therefore:

\[
4\sqrt{x} + 4\sqrt{x + 21} = 84
\]

4. Solve the equation

Divide all terms by 4.
\[
\sqrt{x} + \sqrt{x + 21} = 21
\]

Isolate one of the radical expressions.

\[
\sqrt{x + 21} = 21 - \sqrt{x}
\]

Square both sides.

\[
\left( \sqrt{x + 21} \right)^2 = (21 - \sqrt{x})^2
\]

Eliminate parentheses.

\[
x + 21 = 441 - 42 \sqrt{x} + x
\]

Isolate the radical expression.

\[
42 \sqrt{x} = 420
\]

Divide both sides by 42.

\[
\sqrt{x} = 10
\]

Square both sides.

\[
x = 100 \text{ ft}^2
\]

5. Check

\[
4 \sqrt{100 + 4 \sqrt{100 + 21}} = 40 + 44 = 84
\]

The solution checks out.

Fred’s garden is 10 ft \times 10 \text{ ft} = 100 \text{ ft}^2 and Anita’s garden is 11 \text{ ft} \times 11 \text{ ft} = 121 \text{ ft}^2.

Example 7

A sphere has a volume of 456 cm\(^3\). If the radius of the sphere is increased by 2 cm, what is the new volume of the sphere?
Solution

1. **Make a sketch.** Let’s draw a sphere.
2. **Define variables.** Let $R =$ the radius of the sphere.
3. **Find an equation.**

The volume of a sphere is given by the formula:

$$V = \frac{4}{3}\pi r^3$$

4. **Solve the equation.**

Plug in the value of the volume.

$$456 = \frac{4}{3}\pi r^3$$

Multiply by 3.

$$1368 = 4\pi r^3$$

Divide by $4\pi$.

$$108.92 = r^3$$

Take the cube root of each side.

$$r = \sqrt[3]{108.92} \Rightarrow r = 4.776 \text{ cm}$$

The new radius is 2 centimeters more.

$$r = 6.776 \text{ cm}$$
The new volume is:

\[ V = \frac{4}{3} \pi (6.776)^3 = 1302.5 \text{ cm}^3 \]

5. Check

Let’s substitute in the values of the radius into the volume formula.

\[ V = \frac{4}{3} \pi r^3 = \frac{4}{3} \pi (4.776)^3 = 456 \text{ cm}^3. \]

The solution checks.

Example 8

The kinetic energy of an object of mass m and velocity \( v \) is given by the formula \( KE = \frac{1}{2}mv^2 \). A baseball has a mass of 145 kg and its kinetic energy is measured to be 654 Joules (1 Joule = 1 kg \cdot m^2/s^2) when it hits the catcher’s glove. What is the velocity of the ball when it hits the catcher’s glove?

Solution

1. Start with the formula. \( KE = \frac{1}{2}mv^2 \)
2. Plug in the values for the mass and the kinetic energy. \( 654 \text{ kg} \cdot \text{m}^2/\text{s}^2 = \frac{1}{2}(145 \text{ kg})v^2 \)
3. Multiply both sides by 2. \( 1308 \text{ kg} \cdot \text{m}^2/\text{s}^2 = (145 \text{ kg})v^2 \)
4. Divide both sides by 145 kg. \( 9.02 \text{ m}^2/\text{s}^2 = v^2 \)
5. Take the square root of both sides. \( v = \sqrt{9.02} \sqrt{\frac{\text{m}^2}{\text{s}^2}} = 3.003 \text{ m/s} \)
6. Check Plug the values for the mass and the velocity into the energy formula.

\[ KE = \frac{1}{2}mv^2 = \frac{1}{2}(145 \text{ kg})(3.003 \text{ m/s})^2 = 654 \text{ kg} \cdot \text{m}^2/\text{s}^2 \]
Learning Objectives

- Write square roots with negative radicands in terms of $i$
- Describe the relationship between the sets of integers, rational numbers, real numbers and complex numbers

Introduction

When working with quadratic equations, some quadratic equations have solutions that are not real. For example, an equation such as:

$$x^2 + 1 = 0$$

does not have real solutions. No matter which method of solving quadratics we use, the solutions to that equation are not real numbers.

$$x^2 + 1 = 0$$

$$x^2 = -1$$

It is not possible to square a number and the result is negative. We say that $x^2 + 1 = 0$ has no real solutions. However, by introducing complex numbers we can solve such equations.

The **Imaginary number** $i$ is the number whose square is -1. That is

$$i^2 = -1$$

or

$$i = \sqrt{-1}$$

Recall that you can simplify radicals by factoring out perfect squares in the radicand. For instance, $\sqrt{8} = \sqrt{4 \cdot 2} = \sqrt{4} \sqrt{2} = 2 \sqrt{2}$. The same procedure works with $i$. If you have a negative number in the radicand, you can factor out the -1 and use the identity $i = \sqrt{-1}$ to simplify.

**Example:** Simplify $\sqrt{-5}$

Solution:

$$\sqrt{-5} = \sqrt{(-1) \cdot (5)}$$

$$= \sqrt{-1} \sqrt{5}$$

$$= i \sqrt{5} \text{ or } \sqrt{5}i$$

This also works in combination with the other method of factoring out perfect squares. See the following example. Notice the $i$ can go before the square root or after the square root. However, the $i$ cannot go under the square root.

**Example:** Simplify $\sqrt{-72}$
Solution:
\[\sqrt{-72} = \sqrt{(-1) \cdot (72)}\]
\[= \sqrt{-1} \sqrt{72}\]
\[= i \sqrt{72}\]

But, we’re not done yet. 72 = 36 \cdot 2, so
\[i \sqrt{72} = i \sqrt{36} \sqrt{2}\]
\[= i(6) \sqrt{2}\]
\[= 6i \sqrt{2}\text{ or } 6 \sqrt{2}i\]
# Quadratic Functions

Quadratics - Graphs of Quadratics

Objective: Graph quadratic equations using the vertex, x-intercepts, and y-intercept.

Just as we drew pictures of the solutions for lines or linear equations, we can draw a picture of solution to quadratics as well. One way we can do that is to make a table of values.

Example 1.

\[ y = x^2 - 4x + 3 \]

Make a table of values

<table>
<thead>
<tr>
<th>( x )</th>
<th>( y )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>-2</td>
</tr>
<tr>
<td>2</td>
<td>-3</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>

We will test 5 values to get an idea of shape

\[ y = (0)^2 + 4(0) + 3 = 0 - 0 + 3 = 3 \] Plug 0 in for \( x \) and evaluate
\[ y = (1)^2 - 4(1) + 3 = 1 - 4 + 3 = 0 \] Plug 1 in for \( x \) and evaluate
\[ y = (2)^2 - 4(2) + 3 = 4 - 8 + 3 = -1 \] Plug 2 in for \( x \) and evaluate
\[ y = (3)^2 - 4(3) + 3 = 9 - 12 + 3 = 0 \] Plug 3 in for \( x \) and evaluate
\[ y = (4)^2 - 4(4) + 3 = 16 - 16 + 3 = 3 \] Plug 4 in for \( x \) and evaluate

Our completed table. Plot points on graph

<table>
<thead>
<tr>
<th>( x )</th>
<th>( y )</th>

<tr>
<td>2</td>
<td>-1</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
</tr>
</tbody>
</table>

Plot the points (0, 3), (1, 0), (2, -1), (3, 0), and (4, 3).

Connect the dots with a smooth curve.

Our Solution

When we have \( x^2 \) in our equations, the graph will no longer be a straight line. Quadratics have a graph that looks like a U shape that is called a parabola.
The above method to graph a parabola works for any equation, however, it can be very tedious to find all the correct points to get the correct bend and shape. For this reason we identify several key points on a graph and in the equation to help us graph parabolas more efficiently. These key points are described below.

Point A: y-intercept: Where the graph crosses the vertical y-axis.

Points B and C: x-intercepts: Where the graph crosses the horizontal x-axis.

Point D: Vertex: The point where the graph curves and changes direction.

We will use the following method to find each of the points on our parabola.

To graph the equation \( y = ax^2 + bx + c \), find the following points:

1. y-intercept: Found by making \( x = 0 \), this simplifies down to \( y = c \)

2. x-intercepts: Found by making \( y = 0 \), this means solving \( 0 = ax^2 + bx + c \)

3. Vertex: Let \( x = \frac{-b}{2a} \) to find \( x \). Then plug this value into the equation to find \( y \).

After finding these points we can connect the dots with a smooth curve to find our graph!

Example 2.

\[ y = x^2 + 4x + 3 \]

Find the key points

\[ y = 3 \quad y = c \text{ is the } y \text{-intercept} \]

\[ 0 = x^2 + 4x + 3 \]

To find x-intercepts we solve the equation

\[ 0 = (x + 3)(x + 1) \]

Factor

\[ x + 3 = 0 \quad \text{and} \quad x + 1 = 0 \]

Set each factor equal to zero

\[ x = -3 \quad \text{and} \quad x = -1 \]

Our x-intercepts

\[ x = \frac{-4}{2(1)} = -2 \]

To find the vertex, first use \( x = \frac{-b}{2a} \)

\[ y = (-2)^2 + 4(-2) + 3 \]

Plug this answer into equation to find \( y \)-coordinate

\[ y = 4 - 8 + 3 \]

Evaluate

\[ y = -1 \]

The \( y \)-coordinate

\[ (-2, -1) \]

Vertex as a point

\[ 140 \]
Graph the y-intercept at 3, the x-intercepts at −3 and −1, and the vertex at \((-2, -1)\). Connect the dots with a smooth curve in a U shape to get our parabola.

Our Solution

If the \(a\) in \(y = ax^2 + bx + c\) is a negative value, the parabola will end up being an upside-down U. The process to graph it is identical, we just need to be very careful of how our signs operate. Remember, if \(a\) is negative, then \(ax^2\) will also be negative because we only square the \(x\), not the \(a\).

Example 3.

\[ y = -3x^2 + 12x - 9 \quad \text{Find key points} \]

\[ y = -9 \quad y - \text{intercept is} \ y = c \]

\[ 0 = -3x^2 + 12x - 9 \quad \text{To find} \ x - \text{intercept solve this equation} \]

\[ 0 = -3(x^2 - 4x + 3) \quad \text{Factor out GCF first, then factor rest} \]

\[ 0 = -3(x - 3)(x - 1) \quad \text{Set each factor with a variable equal to zero} \]

\[ x - 3 = 0 \quad \text{and} \quad x - 1 = 0 \quad \text{Solve each equation} \]

\[ \pm 3 \pm 3 \quad \pm 1 \pm 1 \]

\[ x = 3 \quad \text{and} \quad x = 1 \quad \text{Our} \ x - \text{intercepts} \]

\[ x = \frac{-12}{2(-3)} = \frac{-12}{-6} = 2 \quad \text{To find the vertex, first use} \ x = \frac{-b}{2a} \]

\[ y = -3(2)^2 + 12(2) - 9 \quad \text{Plug this value into equation to find} \ y - \text{coordinate} \]

\[ y = -3(4) + 24 - 9 \quad \text{Evaluate} \]

\[ y = -12 + 24 - 9 \]

\[ y = 3 \quad y - \text{value of vertex} \]

\[ (2, 3) \quad \text{Vertex as a point} \]

Graph the y-intercept at −9, the x-intercepts at 3 and 1, and the vertex at \((2, 3)\). Connect the dots with smooth curve in an upside-down U shape to get our parabola.

Our Solution
It is important to remember the graph of all quadratics is a parabola with the same U shape (they could be upside-down). If you plot your points and we cannot connect them in the correct U shape then one of your points must be wrong. Go back and check your work to be sure they are correct!

Just as all quadratics (equation with $y = x^2$) all have the same U-shape to them and all linear equations (equations such as $y = x$) have the same line shape when graphed, different equations have different shapes to them. Below are some common equations (some we have yet to cover!) with their graph shape drawn.

Learning Objectives

- Identify the number of solutions of quadratic equations.
- Solve quadratic equations by graphing.
- Find or approximate zeros of quadratic functions.
- Analyze quadratic functions using a graphing calculators.
- Solve real-world problems by graphing quadratic functions.

Introduction

In the last section you learned how to graph quadratic equations. You saw that finding the $x-$intercepts of a parabola is important because it tells us where the graph crosses the $x-$axis. and it also lets us find the vertex of the parabola. When we are asked to find the solutions of the quadratic equation in the form $ax^2 + bx + c = 0$, we are basically asked to find the $x-$intercepts of the graph of the quadratic function.

Finding the $x-$intercepts of a parabola is also called finding the roots or zeros of the function.

Identify the Number of Solutions of Quadratic Equations

The graph of a quadratic equation is very useful in helping us identify how many solutions and what types of solutions a function has. There are three different situations that occur when graphing a quadratic function.

Case 1 The parabola crosses the $x-$axis at two points.

An example of this is $y = x^2 + x - 6$.

We can find the solutions to equation $x^2 + x - 6 = 0$ by setting $y = 0$. We solve the equation by factoring $(x + 3)(x - 2) = 0$ so $x = -3$ or $x = 2$.

Another way to find the solutions is to graph the function and read the $x-$intercepts from the graph. We see that the parabola crosses the $x-$axis at $x = -3$ and $x = 2$.

When the graph of a quadratic function crosses the $x-$axis at two points, we get two distinct solutions to the quadratic equation.
4.2. Solving Quadratic Equations by Graphing

Case 2 The parabola touches the \(x\)-axis at one point.

An example of this is \(y = x^2 - 2x + 1\).

We can also solve this equation by factoring. If we set \(y = 0\) and factor, we obtain \((x - 1)^2\) so \(x = 1\).

Since the quadratic function is a perfect square, we obtain only one solution for the equation.

Above is what the graph of this function looks like. We see that the graph touches the \(x\)-axis at point \(x = 1\).

When the graph of a quadratic function touches the \(x\)-axis at one point, the quadratic equation has one solution and the solution is called a double root. We can say the root has multiplicity of 2.

Case 3 The parabola does not cross or touch the \(x\)-axis.

An example of this is \(y = x^2 + 4\). If we set \(y = 0\) we get \(x^2 + 4 = 0\). This quadratic polynomial does not factor and the equation \(x^2 = -4\) has no real solutions. When we look at the graph of this function, we see that the parabola does not cross or touch the \(x\)-axis.

When the graph of a quadratic function does not cross or touch the \(x\)-axis, the quadratic equation has no real solutions.

Solve Quadratic Equations by Graphing.

So far we have found the solutions to graphing equations using factoring. However, there are very few functions in real life that factor easily. As you just saw, graphing the function gives a lot of information about the solutions. We can find exact or approximate solutions to quadratic equations by graphing the function associated with it.

Example 1
Find the solutions to the following quadratic equations by graphing.

a) \(-x^2 + 3 = 0\)

b) \(2x^2 + 5x - 7 = 0\)

c) \(-x^2 + x - 3 = 0\)

Solution

Let’s graph each equation. Unfortunately none of these functions can be rewritten in intercept form because we cannot factor the right hand side. This means that you cannot find the \(x\)–intercept and vertex before graphing since you have not learned methods other than factoring.

a) To find the solution to \(-x^2 + 3 = 0\), we need to find the \(x\)–intercepts of \(y = -x^2 + 3\).

Let’s make a table of values so we can graph the function.

\[
\begin{array}{|c|c|}
\hline
x & y = -x^2 + 3 \\
\hline
-3 & y = -(3)^2 + 3 = -6 \\
-2 & y = -(2)^2 + 3 = -1 \\
-1 & y = -(1)^2 + 3 = 2 \\
0 & y = (0)^2 + 3 = 3 \\
1 & y = -(1)^2 + 3 = 2 \\
2 & y = -(2)^2 + 3 = -1 \\
3 & y = -(3)^2 + 3 = -6 \\
\hline
\end{array}
\]

We plot the points and get the following graph:

From the graph we can read that the \(x\)–intercepts are approximately \(x \approx 1.7\) and \(x \approx -1.7\).

These are the solutions to the equation \(-x^2 + 3 = 0\).

b) To solve the equation \(2x^2 + 5x - 7 = 0\) we need to find the \(x\)–intercepts of \(y = 2x^2 + 5x - 7\).

Let’s make a table of values so we can graph the function.

\[
y = 2x^2 + 5x - 7
\]
4.2. Solving Quadratic Equations by Graphing

**Table 4.2:**

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>−3</td>
<td>$y = 2(-3)^2 + 5(-3) - 7 = −4$</td>
</tr>
<tr>
<td>−2</td>
<td>$y = 2(-2)^2 + 5(-2) - 7 = −9$</td>
</tr>
<tr>
<td>−1</td>
<td>$y = 2(-1)^2 + 5(-1) - 7 = −10$</td>
</tr>
<tr>
<td>0</td>
<td>$y = 2(0)^2 + 5(0) - 7 = −7$</td>
</tr>
<tr>
<td>1</td>
<td>$y = 2(1)^2 + 5(1) - 7 = 0$</td>
</tr>
<tr>
<td>2</td>
<td>$y = 2(2)^2 + 5(2) - 7 = 11$</td>
</tr>
<tr>
<td>3</td>
<td>$y = 2(3)^2 + 5(3) - 7 = 26$</td>
</tr>
</tbody>
</table>

We plot the points and get the following graph:

![Graph of quadratic equation](image)

Since we can only see one $x$–intercept on this graph, we need to pick more points smaller than $x = −3$ and re-draw the graph.

$y = 2x^2 + 5x − 7$

**Table 4.3:**

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>−5</td>
<td>$y = 2(-5)^2 + 5(-5) - 7 = 18$</td>
</tr>
<tr>
<td>−4</td>
<td>$y = 2(-4)^2 + 5(-4) - 7 = 5$</td>
</tr>
</tbody>
</table>

Here is the graph again with both $x$–intercepts showing:
From the graph we can read that the $x$–intercepts are $x = 1$ and $x = -3.5$.

These are the solutions to equation $2x^2 + 5x - 7 = 0$.

c) To solve the equation $-x^2 + x - 3 = 0$ we need to find the $x$–intercepts of $y = -x^2 + x - 3$.

Let’s make a table of values so we can graph the function.

$$y = -x^2 + x - 3$$

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>$y = -(−3)^2 + (−3) - 3 = -15$</td>
</tr>
<tr>
<td>-2</td>
<td>$y = -(−2)^2 + (−2) - 3 = -9$</td>
</tr>
<tr>
<td>-1</td>
<td>$y = -(−1)^2 + (−1) - 3 = -5$</td>
</tr>
<tr>
<td>0</td>
<td>$y = -(0)^2 + (0) - 3 = -3$</td>
</tr>
<tr>
<td>1</td>
<td>$y = -(1)^2 + (1) - 3 = -3$</td>
</tr>
<tr>
<td>2</td>
<td>$y = -(−2)^2 + (2) - 3 = -5$</td>
</tr>
<tr>
<td>3</td>
<td>$y = -(3)^2 + (3) - 3 = -9$</td>
</tr>
</tbody>
</table>

We plot the points and get the following graph:

This graph has no $x$–intercepts, so the equation $-x^2 + x - 3 = 0$ has no real solutions.
Find or Approximate Zeros of Quadratic Functions

From the graph of a quadratic function $y = ax^2 + bx + c$, we can find the roots or zeros of the function. The zeros are also the $x$-intercepts of the graph, and they solve the equation $ax^2 + bx + c = 0$. When the zeros of the function are integer values, it is easy to obtain exact values from reading the graph. When the zeros are not integers we must approximate their value.

Let’s do more examples of finding zeros of quadratic functions.

Example 2 Find the zeros of the following quadratic functions.

a) $y = -x^2 + 4x - 4$

b) $y = 3x^2 - 5x$

Solution

a) Graph the function $y = -x^2 + 4x - 4$ and read the values of the $x$-intercepts from the graph.

Let’s make a table of values.

$y = -x^2 + 4x - 4$

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>$y = -(-3)^2 + 4(-3) - 4 = -25$</td>
</tr>
<tr>
<td>-2</td>
<td>$y = -(-2)^2 + 4(-2) - 4 = -16$</td>
</tr>
<tr>
<td>-1</td>
<td>$y = -(-1)^2 + 4(-1) - 4 = -9$</td>
</tr>
<tr>
<td>0</td>
<td>$y = -(0)^2 + 4(0) - 4 = -4$</td>
</tr>
<tr>
<td>1</td>
<td>$y = -(1)^2 + 4(1) - 4 = -1$</td>
</tr>
<tr>
<td>2</td>
<td>$y = -(2)^2 + 4(2) - 4 = 0$</td>
</tr>
<tr>
<td>3</td>
<td>$y = -(3)^2 + 4(3) - 4 = -1$</td>
</tr>
<tr>
<td>4</td>
<td>$y = -(4)^2 + 4(4) - 4 = -4$</td>
</tr>
<tr>
<td>5</td>
<td>$y = -(5)^2 + 4(5) - 4 = -9$</td>
</tr>
</tbody>
</table>

Here is the graph of this function.

The function has a double root at $x = 2$.

b) Graph the function $y = 3x^2 - 5x$ and read the $x$-intercepts from the graph.
Let’s make a table of values.

\[ y = 3x^2 - 5x \]

**Table 4.6:**

<table>
<thead>
<tr>
<th>(x)</th>
<th>(y)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>(y = 3(-3)^2 - 5(-3) = 42)</td>
</tr>
<tr>
<td>-2</td>
<td>(y = 3(-2)^2 - 5(-2) = 22)</td>
</tr>
<tr>
<td>-1</td>
<td>(y = 3(-1)^2 - 5(-1) = 8)</td>
</tr>
<tr>
<td>0</td>
<td>(y = 3(0)^2 - 5(0) = 0)</td>
</tr>
<tr>
<td>1</td>
<td>(y = 3(1)^2 - 5(1) = -2)</td>
</tr>
<tr>
<td>2</td>
<td>(y = 3(2)^2 - 5(2) = 2)</td>
</tr>
<tr>
<td>3</td>
<td>(y = 3(3)^2 - 5(3) = 12)</td>
</tr>
</tbody>
</table>

Here is the graph of this function.

![Graph of y = 3x^2 - 5x](image)

The function has two roots: \(x = 0\) and \(x \approx 1.7\).

**Analyze Quadratic Functions Using a Graphing Calculator**

A graphing calculator is very useful for graphing quadratic functions. Once the function is graphed, we can use the calculator to find important information such as the roots of the function or the vertex of the function.

**Example 3**

Let’s use the graphing calculator to analyze the graph of \(y = x^2 - 20x + 35\).

1. **Graph** the function.

Press the [Y=] button and enter “\(X^2 - 20X + 35\)” next to [Y1 =]. (Note, \(X\) is one of the buttons on the calculator)
Press the [GRAPH] button. This is the plot you should see. If this is not what you see change the window size. For the graph above, we used window size of XMIN = −10, XMAX = 30 and YMIN = −80, YMAX = 50. To change window size, press the [WINDOW] button.

Find the roots.

Use [2nd] [TRACE] (i.e. ‘calc’ button) and use option ’zero’.
Move cursor to the left of one of the roots and press [ENTER].
Move cursor to the right of the same root and press [ENTER].
Move cursor close to the root and press [ENTER].
The screen will show the value of the root. For the left side root, we obtained \(x = 1.9\).
Repeat the procedure for the other root. For the right side root, we obtained \(x = 18\).

Find the vertex

Use [2nd] [TRACE] and use option ’maximum’ if the vertex is a maximum or option ’minimum’ if the vertex is a minimum.
Move cursor to the left of the vertex and press [ENTER].
Move cursor to the right of the vertex and press [ENTER].
Move cursor close to the vertex and press [ENTER].
The screen will show the \(x\) and \(y\) values of the vertex.
For this example, we obtained \(x = 10\) and \(x = −65\).

**Solve Real-World Problems by Graphing Quadratic Functions**

We will now use the methods we learned so far to solve some examples of real-world problems using quadratic functions.

**Example 4 Projectile motion**

*Andrew is an avid archer. He launches an arrow that takes a parabolic path. Here is the equation of the height \(Oy\) of the ball with respect to time \(t\).*

\[
y = −4.9t^2 + 48t
\]

*Here \(y\) is the height in meters and \(t\) is the time in seconds. Find how long it takes the arrow to come back to the ground.*

**Solution**
Let’s graph the equation by making a table of values.

\[ y = -4.9t^2 + 48t \]

**Table 4.7:**

<table>
<thead>
<tr>
<th>( t )</th>
<th>( y )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(-4.9(0)^2 + 48(0) = 0)</td>
</tr>
<tr>
<td>1</td>
<td>(-4.9(1)^2 + 48(1) = 43.1)</td>
</tr>
<tr>
<td>2</td>
<td>(-4.9(2)^2 + 48(2) = 76.4)</td>
</tr>
<tr>
<td>3</td>
<td>(-4.9(3)^2 + 48(3) = 99.9)</td>
</tr>
<tr>
<td>4</td>
<td>(-4.9(4)^2 + 48(4) = 113.6)</td>
</tr>
<tr>
<td>5</td>
<td>(-4.9(5)^2 + 48(5) = 117.5)</td>
</tr>
<tr>
<td>6</td>
<td>(-4.9(6)^2 + 48(6) = 111.6)</td>
</tr>
<tr>
<td>7</td>
<td>(-4.9(7)^2 + 48(7) = 95.9)</td>
</tr>
<tr>
<td>8</td>
<td>(-4.9(8)^2 + 48(8) = 70.4)</td>
</tr>
<tr>
<td>9</td>
<td>(-4.9(9)^2 + 48(9) = 35.1)</td>
</tr>
<tr>
<td>10</td>
<td>(-4.9(10)^2 + 48(10) = -10)</td>
</tr>
</tbody>
</table>

Here is the graph of the function.

The roots of the function are approximately \( t = 0 \text{ sec} \) and \( t = 9.8 \text{ sec} \). The first root says that at time 0 seconds the height of the arrow is 0 meters. The second root says that it takes approximately 9.8 seconds for the arrow to return back to the ground.
4.3 Solving Quadratic Equations by Square Roots

Learning objectives

- Solve quadratic equations involving perfect squares.
- Approximate solutions of quadratic equations.
- Solve real-world problems using quadratic functions and square roots.

Introduction

So far you know how to solve quadratic equations by factoring. However, this method works only if a quadratic polynomial can be factored. Unfortunately, in practice, most quadratic polynomials are not factorable. In this section you will continue learning new methods that can be used in solving quadratic equations. In particular, we will examine equations in which we can take the square root of both sides of the equation in order to arrive at the solution(s).

Solve Quadratic Equations Involving Perfect Squares

Let’s first examine quadratic equations of the type

\[ x^2 - c = 0 \]

We can solve this equation by isolating the \( x^2 \) term: \( x^2 = c \)

Once the \( x^2 \) term is isolated we can take the square root of both sides of the equation since the \( x \)-term has degree 2. Remember that when we take the square root we get two answers: the positive square root and the negative square root:

\[ x = \sqrt{c} \quad \text{and} \quad x = -\sqrt{c} \]

Often this is written as \( x = \pm \sqrt{c} \).

For the equation

\[ x^2 + c = 0 \]

We can solve this equation by isolating the \( x^2 \) term: \( x^2 = -c \)

Once the \( x^2 \) term is isolated we can take the square root of both sides of the equation. Remember that when we take the square root we get two answers: the positive square root and the negative square root:

\[ x = \sqrt{-c} = i \sqrt{c} \quad \text{and} \quad x = -\sqrt{-c} = i \sqrt{c} \]
Often this is written as $x = \pm i \sqrt{c}$.

**Example 1**

*Solve the following quadratic equations.*

a) $x^2 - 4 = 0$

b) $x^2 - 25 = 0$

**Solution**

a) $x^2 - 4 = 0$

Isolate the $x^2$ term:

$x^2 = 4$

Take the square root of both sides:

$x = \sqrt{4}$ and $x = -\sqrt{4}$

**Answer** $x = 2$ and $x = -2$

b) $x^2 - 25 = 0$

Isolate the $x^2$ term:

$x^2 = 25$

Take the square root of both sides:

$x = \sqrt{25} = 5$ and $x = -\sqrt{25} = -5$

**Answer** $x = 5$ and $x = -5$

Another type of equation where we can find the solution using the square root is

$$ax^2 - c = 0$$

We can solve this equation by isolating the $x^2$ term:

$$ax^2 = c$$

$$x^2 = \frac{c}{a}$$

Now we can take the square root of both sides of the equation.

$$x = \sqrt{\frac{c}{a}}$$

and

$$x = -\sqrt{\frac{c}{a}}$$

Often this is written as $x = \pm \sqrt{\frac{c}{a}}$.

**Example 2**

*Solve the following quadratic equations.*

a) $9x^2 - 16 = 0$

b) $81x^2 - 1 = 0$

**Solution**

a) $9x^2 - 16 = 0$
4.3. Solving Quadratic Equations by Square Roots

Isolate the \(x^2\).

\[9x^2 = 16\]
\[x^2 = \frac{16}{9}\]

Take the square root of both sides. \(x = \sqrt{\frac{16}{9}} = \frac{4}{3}\) and \(x = -\sqrt{\frac{16}{9}} = -\frac{4}{3}\)

**Answer:** \(x = \frac{4}{3}\) and \(x = -\frac{4}{3}\)

b) \(81x^2 - 1 = 0\)

Isolate the \(x^2\)

\[81x^2 = 1\]
\[x^2 = \frac{1}{81}\]

Take the square root of both sides \(x = \sqrt{\frac{1}{81}} = \frac{1}{9}\) and \(x = -\sqrt{\frac{1}{81}} = -\frac{1}{9}\)

**Answer:** \(x = \frac{1}{9}\) and \(x = -\frac{1}{9}\)

As you have seen previously, some quadratic equations have no real solutions.

**Example 3**

**Solve the following quadratic equations.**

a) \(x^2 + 1 = 0\)

b) \(4x^2 + 9 = 0\)

**Solution**

a) \(x^2 + 1 = 0\)

Isolate the \(x^2\)

\[x^2 = -1\]

Take the square root of both sides: \(x = \sqrt{-1} = i\) and \(x = -\sqrt{-1} = -i\) or \(x = \pm i\)

**Answer** Square roots of negative numbers do not give real number results, so there are **no real solutions** to this equation. The solutions are **complex numbers**.

b) \(4x^2 + 9 = 0\)

Isolate the \(x^2\)

\[4x^2 = -9\]
\[x^2 = \frac{-9}{4}\]

Take the square root of both sides \(x = \sqrt{-\frac{9}{4}} = \frac{3}{2}i\) and \(x = -\sqrt{-\frac{9}{4}} = -\frac{3}{2}i\)

**Answer** There are **no real solutions**. The solutions are **complex numbers**.

We can also use the square root function in some quadratic equations where one side of the equation is a perfect square. This is true if an equation is of the form...
\[(x - 2)^2 = 9\]

Both sides of the equation are perfect squares. We take the square root of both sides.
\[x - 2 = 3 \text{ and } x - 2 = -3\]
Solve both equations

**Answer:** \(x = 5\) and \(x = -1\)

Notice if we graph set the equation equal to 0 by subtracting 9 on both sides we get:

\[(x - 2)^2 - 9 = 0\]

Now if we graph:

\[y = (x - 2)^2 - 9\]

the points where \(y = 0\) are the \(x\)-values that solve our equation. The points on a function where \(y = 0\), are the \(x\)-intercepts. Notice the graph of \(y = (x - 2)^2 - 9\) has \(x\)-intercepts of (5, 0) and (-1,0), which are also the solutions to the equation. You can use this technique to check the solutions to quadratic equations as long as the quadratic equation has real solutions. If a quadratic equation has complex solutions with an imaginary part, the graph will not cross the \(x\)-axis.

**Example 4**

Solve the following quadratic equations.

a) \((x - 1)^2 = 4\)

b) \((x + 3)^2 = -16\)

**Solution**

a) \((x - 1)^2 = 4\)

Take the square root of both sides. \(x - 1 = 2\) and \(x - 1 = -2\)
Solve each equation. \(x = 3\) and \(x = -1\)

**Answer:** \(x = 3\) and \(x = -1\)

b) \((x + 3)^2 = -16\)

Take the square root of both sides. \(x + 3 = 4i\) and \(x + 3 = -4i\)
Solve each equation. \(x = -3 + 4i\) and \(x = -3 - 4i\)

It might be necessary to factor the left side of the equation as a perfect square before applying the method outlined above.

**Example 5**

Solve the following quadratic equations.
4.3. Solving Quadratic Equations by Square Roots

a) \(x^2 + 8x + 16 = 25\)
b) \(4x^2 - 40x + 25 = -9\)

Solution

a) \(x^2 + 8x + 16 = 25\)

Factor the right hand side. \(x^2 + 8x + 16 = (x + 4)^2\) so \((x + 4)^2 = 25\)

Take the square root of both sides. \(x + 4 = 5\) and \(x + 4 = -5\)

Solve each equation. \(x = 1\) and \(x = -9\)

Answer \(x = 1\) and \(x = -9\)

b) \(4x^2 - 20x + 25 = -9\)

Factor the right hand side. \(4x^2 - 20x + 25 = (2x - 5)^2\) so \((2x - 5)^2 = -9\)

Take the square root of both sides. \(2x - 5 = 3i\) and \(2x - 5 = -3i\)

Solve each equation. \(x = \frac{5 + 3i}{2}\) and \(x = \frac{5 - 3i}{2}\)

Answer \(x = \frac{5}{2} + \frac{3i}{2}\) and \(x = \frac{5}{2} - \frac{3i}{2}\)

Approximate Solutions of Quadratic Equations

We use the methods we learned so far in this section to find approximate solutions to quadratic equations. We can get approximate solutions when taking the square root does not give an exact answer.

Example 6

Solve the following quadratic equations.
a) \(x^2 - 3 = 0\)
b) \(2x^2 - 9 = 0\)

Solution

a)

Isolate the \(x^2\). \(x^2 = 3\)

Take the square root of both sides. \(x = \sqrt{3}\) and \(x = -\sqrt{3}\)

Answer \(x \approx 1.73\) and \(x \approx -1.73\)

b)

Isolate the \(x^2\). \(2x^2 = 9\) so \(x^2 = \frac{9}{2}\)

Take the square root of both sides. \(x = \sqrt{\frac{9}{2}} = \frac{3}{\sqrt{2}}\) and \(x = -\sqrt{\frac{9}{2}} = -\frac{3}{\sqrt{2}}\)
Answer \( x \approx 2.12 \) and \( x \approx -2.12 \)

Example 7

Solve the following quadratic equations.
a) \((2x + 5)^2 = 10\)
b) \(x^2 - 2x + 1 = 5\)

Solution.
a) 

Take the square root of both sides. \[ 2x + 5 = \sqrt{10} \text{ and } 2x + 5 = -\sqrt{10} \]

Solve both equations.

\[
\begin{align*}
\frac{-5 + \sqrt{10}}{2} \quad \text{and} \quad \frac{-5 - \sqrt{10}}{2}
\end{align*}
\]

Answer \( x \approx -0.92 \) and \( x \approx -4.08 \)

b) 

Factor the right hand side. \((x - 1)^2 = 5\)

Take the square root of both sides. \[ x - 1 = \sqrt{5} \text{ and } x - 1 = -\sqrt{5} \]

Solve each equation.

\[
\begin{align*}
x = 1 + \sqrt{5} \quad \text{and} \quad x = 1 - \sqrt{5}
\end{align*}
\]

Answer \( x \approx 3.24 \) and \( x \approx -1.24 \)

Solve Real-World Problems Using Quadratic Functions and Square Roots

There are many real-world problems that require the use of quadratic equations in order to arrive at the solution. In this section, we will examine problems about objects falling under the influence of gravity. When objects are dropped from a height, they have no initial velocity and the force that makes them move towards the ground is due to gravity. The acceleration of gravity on earth is given by

\[ g = -9.8 \frac{m}{s^2} \quad \text{or} \quad g = -32 \frac{ft}{s^2} \]

The negative sign indicates a downward direction. We can assume that gravity is constant for the problems we will be examining, because we will be staying close to the surface of the earth. The acceleration of gravity decreases as an object moves very far from the earth. It is also different on other celestial bodies such as the Moon.

The equation that shows the height of an object in free fall is given by

\[ y = \frac{1}{2} gt^2 + y_0 \]

The term \( y_0 \) represents the initial height of the object \( t \) is time, and \( g \) is the force of gravity. There are two choices for the equation you can use.

\[
\begin{align*}
y &= -4.9t^2 + y_0 \quad \text{If you wish to have the height in meters.} \\
y &= -16t^2 + y_0 \quad \text{If you wish to have the height in feet.}
\end{align*}
\]
Example 8 Free fall

How long does it take a ball to fall from a roof to the ground 25 feet below?

Solution

Since we are given the height in feet, use equation

\[ y = -16t^2 + y_0 \]

The initial height is \( y_0 = 25 \text{ feet} \), so

\[ y = -16t^2 + 25 \]

The height when the ball hits the ground is \( y = 0 \), so

\[ 0 = -16t^2 + 25 \]

Solve for \( t \)

\[ 16t^2 = 25 \]

\[ t^2 = \frac{25}{16} \]

\[ t = \frac{5}{4} \text{ or } t = -\frac{5}{4} \]

We can discard the solution \( t = -\frac{5}{4} \) since only positive values for time makes sense in this case,

Answer: It takes the ball 1.25 seconds to fall to the ground.

Example 9 Free fall

A rock is dropped from the top of a cliff and strikes the ground 7.2 seconds later. How high is the cliff in meters?

Solution

Since we want the height in meters, use equation

\[ y = -4.9t^2 + y_0 \]

The time of flight is \( t = 7.2 \text{ seconds} \)

The height when the ball hits the ground is \( y = 0 \), so

\[ 0 = -4.9(7.2)^2 + y_0 \]

Simplify

\[ 0 = -254 + y_0 \text{ so } y_0 = 254 \]

Answer: The cliff is 254 meters high.

Example 10

Victor drops an apple out of a window on the 10th floor which is 120 feet above ground. One second later Juan drops an orange out of a 6th floor window which is 72 feet above the ground. Which fruit reaches the ground first? What is the time difference between the fruits’ arrival to the ground?

Solution

Let’s find the time of flight for each piece of fruit.

For the Apple we have the following.

Since we have the height in feet, use equation

\[ y = -16t^2 + y_0 \]

The initial height \( y_0 = 120 \text{ feet} \).

The height when the ball hits the ground is \( y = 0 \), so

\[ 0 = -16t^2 + 120 \]

Solve for \( t \)

\[ 16t^2 = 120 \]

\[ t^2 = \frac{120}{16} = 7.5 \]

\[ t = 2.74 \text{ or } t = -2.74 \text{ seconds}. \]

For the orange we have the following.
The initial height $y_0 = 72$ feet.

Solve for $t$.

\[0 = -16t^2 + 72\]

\[16t^2 = 72\]

\[t^2 = \frac{72}{16} = 4.5\]

\[t = 2.12 \text{ or } t = -2.12 \text{ seconds}\]

But, don’t forget that the orange was thrown out one second later, so add one second to the time of the orange. It hit the ground 3.12 seconds after Victor dropped the apple.

**Answer** The apple hits the ground first. It hits the ground 0.38 seconds before the orange. (Hopefully nobody was on the ground at the time of this experiment.)
4.4 Solving Quadratic Equations using the Quadratic Formula

Learning objectives

- Solve quadratic equations using the quadratic formula.
- Identify and choose methods for solving quadratic equations.
- Solve real-world problems using functions by completing the square.

Introduction

In this section, you will solve quadratic equations using the Quadratic Formula. Most of you are already familiar with this formula from previous mathematics courses. It is probably the most used method for solving quadratic equations. For a quadratic equation in standard form

\[ ax^2 + bx + c = 0 \]

The solutions are found using the following formula.

\[ x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \]

We will start by explaining where this formula comes from and then show how it is applied. This formula is derived by solving a general quadratic equation using the method of completing the square that you learned in the previous section.

Divide by the coefficient of the \( x^2 \) term:

\[ x^2 + \frac{b}{a}x = -\frac{c}{a} \]

Rewrite:

\[ x^2 + 2 \left( \frac{b}{2a} \right) x = -\frac{c}{a} \]

Add the constant \( \left( \frac{b}{2a} \right)^2 \) to both sides:

\[ x^2 + 2 \left( \frac{b}{2a} \right) x + \left( \frac{b}{2a} \right)^2 = -\frac{c}{a} + \frac{b^2}{4a^2} \]

Factor the perfect square trinomial:

\[ \left( x + \frac{b}{2a} \right)^2 = -\frac{4ac}{4a^2} + \frac{b^2}{4a^2} \]

Simplify:

\[ \left( x + \frac{b}{2a} \right)^2 = \frac{b^2 - 4ac}{4a^2} \]

Take the square root of both sides:

\[ x + \frac{b}{2a} = \pm \frac{b^2 - 4ac}{2a} \]

Simplify:

\[ x = \frac{b}{2a} + \frac{\sqrt{b^2 - 4ac}}{2a} \quad \text{and} \quad x = -\frac{b}{2a} - \frac{\sqrt{b^2 - 4ac}}{2a} \]

160
This can be written more compactly as \( x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}. \)

You can see that the familiar formula comes directly from applying the method of completing the square. Applying
the method of completing the square to solve quadratic equations can be tedious. The quadratic formula is a more straightforward way of finding the solutions.

### Solve Quadratic Equations Using the Quadratic Formula

Applying the quadratic formula basically amounts to plugging the values of \( a, b \) and \( c \) into the quadratic formula.

#### Example 1

**Solve the following quadratic equation using the quadratic formula.**

a) \( 2x^2 + 3x + 1 = 0 \)

b) \( x^2 - 6x + 5 = 0 \)

c) \( -4x^2 + x + 1 = 0 \)

**Solution**

Start with the quadratic formula and plug in the values of \( a, b \) and \( c \).

a)

\[ x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \]

Plug in the values \( a = 2, b = 3, c = 1 \).

\[ x = \frac{-3 \pm \sqrt{(3)^2 - 4(2)(1)}}{2(2)} \]

Simplify.

\[ x = \frac{-3 \pm \sqrt{9 - 8}}{4} = \frac{-3 \pm \sqrt{1}}{4} \]

Separate the two options.

\[ x = \frac{-3 + 1}{4} = -\frac{2}{4} = -\frac{1}{2} \quad \text{and} \quad x = \frac{-3 - 1}{4} = -\frac{4}{4} = -1 \]

**Answer** \( x = -\frac{1}{2} \) and \( x = -1 \)

Remember you can check this solution by determining the \( x \)-intercepts of the quadratic function \( y = 2x^2 + 3x + 1 \).

b)

\[ x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \]

Plug in the values \( a = 1, b = -6, c = 5 \).

\[ x = \frac{-(-6) \pm \sqrt{(-6)^2 - 4(1)(5)}}{2(1)} \]

Simplify.

\[ x = \frac{6 \pm \sqrt{36 - 20}}{2} = \frac{6 \pm \sqrt{16}}{2} \]

Separate the two options.

\[ x = \frac{6 + 4}{2} = 5 \quad \text{and} \quad x = \frac{6 - 4}{2} = 1 \]

**Answer** \( x = 5 \) and \( x = 1 \)
4.4. Solving Quadratic Equations using the Quadratic Formula

Quadratic formula. 
\[ x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \]

Plug in the values \( a = -4, b = 1, c = 1 \). 
\[ x = \frac{-1 \pm \sqrt{(1)^2 - 4(-4)(1)}}{2(-4)} \]
Simplify. 
\[ x = \frac{-1 \pm \sqrt{1 + 16}}{-8} = \frac{-1 \pm \sqrt{17}}{-8} \]
Separate the two options. 
\[ x = \frac{-1 + \sqrt{17}}{-8} \quad \text{and} \quad x = \frac{-1 - \sqrt{17}}{-8} \]

Often when we plug the values of the coefficients into the quadratic formula, we obtain a negative number inside the square root. Since the square root of a negative number does not give real answers, we say that the equation has no real solutions. In more advanced mathematics classes, you will learn how to work with “complex” (or “imaginary”) solutions to quadratic equations.

Example 2

Solve the following quadratic equation using the quadratic formula \( x^2 + 2x + 7 = 0 \)

Solution: 

Quadratic formula. 
\[ x = \frac{b \pm \sqrt{b^2 - 4ac}}{2a} \]

Plug in the values \( a = 1, b = 2, c = 7 \). 
\[ x = \frac{-2 \pm \sqrt{(2)^2 - 4(1)(7)}}{2(1)} \]
Simplify. 
\[ x = \frac{-2 \pm \sqrt{4 - 28}}{2} = \frac{-2 \pm \sqrt{-24}}{2} \]
\[ x = \frac{-2 \pm 2i \sqrt{6}}{2} = -1 \pm i \sqrt{6} \]

To apply the quadratic formula, we must make sure that the equation is written in standard form. For some problems, we must rewrite the equation before we apply the quadratic formula.

Example 3

Solve the following quadratic equation using the quadratic formula.

a) \( x^2 - 6x = 10 \)

b) \( 8x^2 + 5x = -6 \)

Solution:
a) Rewrite the equation in standard form. \(x^2 - 6x - 10 = 0\)

**Quadratic formula**

\[x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\]

Plug in the values \(a = 1, b = -6, c = -10\).

Simplify.

\[x = \frac{6 \pm \sqrt{36 + 40}}{2} = \frac{6 \pm \sqrt{76}}{2} = \frac{6 \pm 2\sqrt{19}}{2} = 3 \pm \sqrt{19}\]

b) Rewrite the equation in standard form. \(8x^2 + 5x + 6 = 0\)

**Quadratic formula**

\[x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\]

Plug in the values \(a = 8, b = 5, c = 6\).

Simplify.

\[x = \frac{-5 \pm \sqrt{25 - 192}}{16} = \frac{-5 \pm \sqrt{-167}}{16} = \frac{-5 \pm i\sqrt{167}}{16}\]

Notice if we try to check this solution by graphing the quadratic function \(y = 8x^2 + 5x + 6\), the graph does not cross the x-axis or have x-intercepts. This verifies we have complex solutions with an imaginary part.

**Finding the Vertex of a Parabola with the Quadratic Formula**

Sometimes you get more information from a formula beyond what you were originally seeking. In this case, the quadratic formula also gives us an easy way to locate the vertex of a parabola.

First, recall that the quadratic formula tells us the **roots** or **solutions** of the equation \(ax^2 + bx + c = 0\). Those roots are

\[x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\]

We can rewrite the fraction in the quadratic formula as

\[x = \frac{-b}{2a} \pm \frac{\sqrt{b^2 - 4ac}}{2a}\]
Recall that the roots are symmetric about the vertex. In the form above, we can see that the roots of a quadratic equation are symmetric around the x–coordinate $-\frac{b}{2a}$ because they move $\sqrt{\frac{b^2-4ac}{4a^2}}$ units to the left and right (recall the ± sign) from the vertical line $x = -\frac{b}{2a}$. The image to the right illustrates this for the equation $x^2 - 2x - 3 = 0$. The roots, -1 and 3 are both 2 units from the vertical line $x = 1$.

**Identify and Choose Methods for Solving Quadratic Equations.**

In mathematics, you will need to solve quadratic equations that describe application problems or that are part of more complicated problems. You learned four ways of solving a quadratic equation.

- Factorizing.
- Taking the square root.
- Completing the square.
- Quadratic formula.

Usually you will not be told which method to use. You will have to make that decision yourself. However, here are some guidelines to which methods are better in different situations.

**Factoring** is always best if the quadratic expression is easily factorable. It is always worthwhile to check if you can factor because this is the fastest method.

**Taking the square root** is best used when there is no $x$ term in the equation.

**Completing the square** can be used to solve any quadratic equation. This is usually not any better than using the quadratic formula (in terms of difficult computations), however it is a very important method for re-writing a quadratic function in vertex form. It is also used to re-write the equations of circles, ellipses and hyperbolas in standard form (something you will do in algebra II, trigonometry, physics, calculus, and beyond...).

**Quadratic formula** is the method that is used most often for solving a quadratic equation if solving directly by taking square root and factoring does not work.

If you are using factoring or the quadratic formula make sure that the equation is in standard form.

**Example 4**

Solve each quadratic equation

a) $x^2 - 4x - 5 = 0$

b) $x^2 = 8$

c) $-4x^2 + x = 2$

d) $25x^2 - 9 = 0$

e) $3x^2 = 8x$

**Solution**

a) This expression is easily factorable so we can factor and apply the zero-product property:

- Factor.
- Apply zero-product property.
- Solve.

$(x - 5)(x + 1) = 0$

$x - 5 = 0$ and $x + 1 = 0$

$x = 5$ and $x = -1$

**Answer** $x = 5$ and $x = -1$

b) Since the expression is missing the $x$ term we can take the square root:
Take the square root of both sides. \( x = \sqrt{8} \) and \( x = -\sqrt{8} \)

**Answer** \( x = 2.83 \) and \( x = -2.83 \)

c) Rewrite the equation in standard form.

It is not apparent right away if the expression is factorable, so we will use the quadratic formula.

\[
\text{Quadratic formula} \quad x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}
\]

Plug in the values \( a = -4, b = 1, c = -2 \).

\[
x = \frac{-1 \pm \sqrt{1^2 - 4(-4)(-2)}}{2(-4)}
\]

Simplify.

\[
x = \frac{-1 \pm \sqrt{1 - 32}}{-8} = \frac{-1 \pm \sqrt{-31}}{-8} = \frac{1 \pm \sqrt{31}i}{8}
\]

**Answer** Two complex solutions: \( x = \frac{1 \pm \sqrt{31}i}{8} = \frac{1}{8} \pm \frac{\sqrt{31}}{8}i \)

d) This problem can be solved easily either with factoring or taking the square root. Let’s take the square root in this case.

\[
\text{Add 9 to both sides of the equation.} \quad 25x^2 = 9
\]

\[
\text{Divide both sides by 25.} \quad x^2 = \frac{9}{25}
\]

\[
\text{Take the square root of both sides.} \quad x = \sqrt{\frac{9}{25}} \text{ and } x = -\sqrt{\frac{9}{25}}
\]

Simplify.

\[
x = \frac{3}{5} \text{ and } x = -\frac{3}{5}
\]

**Answer** \( x = \frac{3}{5} \) and \( x = -\frac{3}{5} \)

e)

Rewrite the equation in standard form

\[
3x^2 - 8x = 0
\]

Factor out common \( x \) term.

\[
x(3x - 8) = 0
\]

Set both terms to zero.

\[
x = 0 \text{ and } 3x = 8
\]

Solve.

\[
x = 0 \text{ and } x = \frac{8}{3}
\]

**Answer** \( x = 0 \) and \( x = \frac{8}{3} \)

**Solve Real-World Problems Using Quadratic Functions by any Method**

Here are some application problems that arise from number relationships and geometry applications.

**Example 5**

*The product of two positive consecutive integers is 156. Find the integers.*

**Solution**
For two consecutive integers, one integer is one more than the other one.

**Define**

Let \( x \) = the smaller integer
\( x + 1 \) = the next integer

**Translate**

The product of the two numbers is 156. We can write the equation:

\[
x(x + 1) = 156
\]

**Solve**

\[
x^2 + x = 156
\]
\[
x^2 + x - 156 = 0
\]

Apply the quadratic formula with \( a = 1 \), \( b = 1 \), \( c = -156 \)

\[
x = -1 \pm \sqrt{1^2 - 4(1)(-156)}
\]
\[
x = -1 \pm \sqrt{625} = -1 \pm 25
\]
\[
x = -1 + 25 \quad \text{and} \quad x = -1 - 25
\]
\[
x = \frac{24}{2} = 12 \quad \text{and} \quad x = \frac{-26}{2} = -13
\]

Since we are looking for positive integers take, \( x = 12 \)

**Answer** 12 and 13

**Check** \( 12 \times 13 = 156 \). The answer checks out.

**Example 6**

The length of a rectangular pool is 10 meters more than its width. The area of the pool is 875 square/meters. Find the dimensions of the pool.

**Solution:**

Draw a sketch

**Define**

Let \( x \) = the width of the pool
\[ x + 10 \text{ = the length of the pool} \]

**Translate**

The area of a rectangle is \( A = \text{length} \times \text{width} \), so

\[ x(x + 10) = 875 \]

**Solve**

\[ x^2 + 10x = 875 \]
\[ x^2 + 10x - 875 = 0 \]

Apply the quadratic formula with \( a = 1, b = 10 \) and \( c = -875 \)

\[ x = \frac{-10 \pm \sqrt{(10)^2 - 4(1)(-875)}}{2(1)} \]
\[ x = \frac{-10 \pm \sqrt{100 + 3500}}{2} \]
\[ x = \frac{-10 \pm \sqrt{3600}}{2} = \frac{-10 \pm 60}{2} \]
\[ x = \frac{50}{2} = 25 \text{ and } x = \frac{-70}{2} = -35 \]

Since the dimensions of the pools should be positive, then \( x = 25 \text{ meters} \).

**Answer** The pool is 25 meters \( \times \) 35 meters.

**Check** \( 25 \times 35 = 875 \text{ m}^2 \). The answer checks out.

**Example 7**

Suzie wants to build a garden that has three separate rectangular sections. She wants to fence around the whole garden and between each section as shown. The plot is twice as long as it is wide and the total area is 200 ft\(^2\). How much fencing does Suzie need?

**Solution**

**Draw a Sketch**

**Define**
Let \( x \) = the width of the plot
\( 2x \) = the length of the plot

**Translate**
Area of a rectangle is \( A = \text{length} \times \text{width}, \) so

\[
x(2x) = 200
\]

**Solve**

\[
2x^2 = 200
\]

Solve by taking the square root.

\[
x^2 = 100
\]
\[
x = \sqrt{100} \quad \text{and} \quad x = -\sqrt{100} \\
x = 10 \quad \text{and} \quad x = -10
\]

We take \( x = 10 \) since only positive dimensions make sense.
The plot of land is 10 feet \( \times \) 20 feet.

To fence the garden the way Suzie wants, we need 2 lengths and 4 widths = 2(20) + 4(10) = 80 feet of fence.

**Answer:** The fence is 80 feet.

**Check** \( 10 \times 20 = 200 \; \text{ft}^2 \) and \( 2(20) + 4(10) = 80 \; \text{feet} \). The answer checks out.

**Example 8**

An isosceles triangle is enclosed in a square so that its base coincides with one of the sides of the square and the tip of the triangle touches the opposite side of the square. If the area of the triangle is 20 in\(^2\) what is the area of the square?

**Solution:**

**Draw a sketch.**

**Define**

Let \( x \) = base of the triangle
\( x \) = height of the triangle
Translate
Area of a triangle is $\frac{1}{2} \times \text{base} \times \text{height}$, so

$$\frac{1}{2} \cdot x \cdot x = 20$$

Solve

$$\frac{1}{2}x^2 = 20$$

Solve by taking the square root.

$$x^2 = 40$$

$$x = \sqrt{40} = 2 \sqrt{10} \text{ and } x = -\sqrt{40} = -2 \sqrt{10}$$

$$x \approx 6.32 \text{ and } x \approx -6.32$$

The side of the square is approximately 6.32 inches.

The area of the square is $(6.32)^2 \approx 40 \text{ in}^2$, twice as big as the area of the triangle.

**Answer:** Area of the triangle is $40 \text{ in}^2$

**Check:** It makes sense that the area of the square will be twice that of the triangle. If you look at the figure you can see that you can fit two triangles inside the square.

The answer checks.
4.5 The Discriminant

Learning Objectives

• Find the discriminant of a quadratic equation.
• Interpret the discriminant of a quadratic equation.
• Solve real-world problems using quadratic functions and interpreting the discriminant.

Introduction

The quadratic equation is \( ax^2 + bx + c = 0 \).

It can be solved using the quadratic formula \( x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \).

The expression inside the square root is called the discriminant, \( D = b^2 - 4ac \). The discriminant can be used to analyze the types of solutions of quadratic equations without actually solving the equation. Here are some guidelines.

• If \( b^2 - 4ac > 0 \), we obtain two separate real solutions.
• If \( b^2 - 4ac < 0 \), we obtain non-real solutions or two complex solutions.
• If \( b^2 - 4ac = 0 \), we obtain one real solution, a double root or a root with multiplicity 2.

Find the Discriminant of a Quadratic Equation

To find the discriminant of a quadratic equation, we calculate \( D = b^2 - 4ac \).

Example 1

Find the discriminant of each quadratic equation. Then tell how many solutions there will be to the quadratic equation without solving.

a) \( x^2 - 5x + 3 = 0 \)

b) \( 4x^2 - 4x + 1 = 0 \)

c) \( -2x^2 + x = 4 \)

Solution:

a) Substitute \( a = 1, b = -5 \) and \( c = 3 \) into the discriminant formula \( D = (-5)^2 - 4(1)(3) = 13 \).

There are two real solutions because \( D > 0 \).

b) Substitute \( a = 4, b = -4 \) and \( c = 1 \) into the discriminant formula \( D = (-4)^2 - 4(4)(1) = 0 \).

There is one real solution because \( D = 0 \).

c) Rewrite the equation in standard form \( -2x^2 + x - 4 = 0 \).

Substitute \( a = -2, b = 1 \) and \( c = -4 \) into the discriminant formula: \( D = (1)^2 - 4(-2)(-4) = -31 \).

There are no real solutions because \( D < 0 \).
Interpret the Discriminant of a Quadratic Equation

The sign of the discriminant tells us the nature of the solutions (or roots) of a quadratic equation. We can obtain two distinct real solutions if $D > 0$ (If $D$ is a perfect square, there are 2 real rational solutions, If $D$ is not a perfect square, there are two irrational real solutions.), no real solutions if $D < 0$ or one solution (called a “double root”) if $D = 0$. Recall that the number of solutions of a quadratic equation tell us how many times a parabola crosses the $x-$axis.

$D = 0$

$D > 0$
4.5. The Discriminant

\[ D < 0 \]

**Example 2**

Determine the nature of solutions of each quadratic equation.

a) \(4x^2 - 1 = 0\)

b) \(10x^2 - 3x = -4\)

c) \(x^2 - 10x + 25 = 0\)

d) \(-3x^2 + 4x + 1 = 0\)

**Solution**

Use the value of the discriminant to determine the nature of the solutions to the quadratic equation.

a) Substitute \(a = 4, b = 0\) and \(c = -1\) into the discriminant formula \(D = (0)^2 - 4(4)(-1) = 16\).

The discriminant is positive, so the equation has two distinct real solutions.

The solutions to the equation are: \(0 \pm \sqrt{16} = 0 \pm 4\).

b) Rewrite the equation in standard form \(10x^2 - 3x + 4 = 0\).

Substitute \(a = 10, b = -3\) and \(c = 4\) into the discriminant formula \(D = (-3)^2 - 4(10)(4) = -151\).

The discriminant is negative, so the equation has two non-real solutions or two complex solutions.

c) Substitute \(a = 1, b = -10\) and \(c = 25\) into the discriminant formula \(D = (-10)^2 - 4(1)(25) = 0\).

The discriminant is 0, so the equation has a double root.

The solution to the equation is \(\frac{10 \pm \sqrt{0}}{2} = \frac{10}{2} = 5\).

If the discriminant is a perfect square, then the solutions to the equation are rational numbers.

d) Substitute \(a = -3, b = 4\) and \(c = 1\) into the discriminant formula \(D = (4)^2 - 4(-3)(1) = 28\).

The discriminant is a positive but not a perfect square, so the solutions are two real irrational numbers.

The solutions to the equation are \(\pm \frac{\sqrt{28}}{6} = \frac{1}{3} \pm \frac{\sqrt{7}}{3}\) so, \(x \approx -0.55\) and \(x \approx 1.22\).

**Example 3**

Determine the nature of the solutions to each quadratic equation.

a) \(2x^2 + x - 3 = 0\)

b) \(5x^2 - x - 1 = 0\)

**Solution**

Use the discriminant to determine the nature of the solutions.

a) Plug \(a = 2, b = 1\) and \(c = -3\) into the discriminant formula: \(D = (1)^2 - 4(2)(-3) = 25\)

The discriminant is a positive perfect square, so the solutions are two real rational numbers.

The solutions to the equation are: \(-\frac{1 \pm \sqrt{25}}{4} = -\frac{1 \pm 5}{4}\), so \(x = 1\) and \(x = -\frac{3}{2}\).

b) Plug \(a = 5, b = -1\) and \(c = -1\) into the discriminant formula: \(D = (-1)^2 - 4(5)(-1) = 21\)

The discriminant is positive but not a perfect square, so the solutions are two real irrational numbers.

The solutions to the equation are: \(\frac{1 \pm \sqrt{21}}{10}\), so \(x \approx 0.56\) and \(x \approx -0.36\).
Solve Real-World Problems Using Quadratic Functions and Interpreting the Discriminant

You saw that calculating the discriminant shows what types of solutions a quadratic equation possesses. Knowing the types of solutions is very useful in applied problems. Consider the following situation.

Example 4

Marcus kicks a football in order to score a field goal. The height of the ball is given by the equation \( y = \frac{-32}{6400}x^2 + x \) where \( y \) is the height and \( x \) is the horizontal distance the ball travels. We want to know if he kicked the ball hard enough to go over the goal post which is 10 feet high.

Solution

Define

Let \( y = \) height of the ball in feet
\( x = \) distance from the ball to the goalpost.

Translate

We want to know if it is possible for the height of the ball to equal 10 feet at some real distance from the goalpost.

\[
10 = \frac{-32}{6400}x^2 + x
\]

Solve

Write the equation in standard form.

\[
-\frac{32}{6400}x^2 + x - 10 = 0
\]

Simplify.

\[
-0.005x^2 + x - 10 = 0
\]

Find the discriminant.

\[
D = (1)^2 - 4(-0.005)(-10) = 0.8
\]

Since the discriminant is positive, we know that it is possible for the ball to go over the goal post, if Marcus kicks it from an acceptable distance \( x \) from the goal post. From what distance can he score a field goal? See the next example.

Example 4 (continuation)

What is the farthest distance that he can kick the ball from and still make it over the goal post?

Solution

We need to solve for the value of \( x \) by using the quadratic formula.

\[
x = \frac{-1 \pm \sqrt{0.8}}{-0.01} \approx 10.6 \text{ or } 189.4
\]

This means that Marcus has to be closer that 189.4 feet or further than 10.6 feet to make the goal. (Why are there two solutions to this equation? Think about the path of a ball after it is kicked).

Example 5

Emma and Bradon own a factory that produces bike helmets. Their accountant says that their profit per year is given by the function

\[
P = 0.003x^2 + 12x + 27760
\]
In this equation $x$ is the number of helmets produced. Their goal is to make a profit of $40,000 this year. Is this possible?

Solution

We want to know if it is possible for the profit to equal $40,000.

\[
40000 = -0.003x^2 + 12x + 27760
\]

Solve

Write the equation in standard form

\[
-0.003x^2 + 12x - 12240 = 0
\]

Find the discriminant.

\[
D = (12)^2 - 4(-0.003)(-12240) = -2.88
\]

Since the discriminant is negative, we know that there are no real solutions to this equation. Thus, it is not possible for Emma and Bradon to make a profit of $40,000 this year no matter how many helmets they make.
4.6 References

1. \( D \) equals zero.
2. \( D \) is greater than zero.
3. \( D \) is less than zero.

Learning Objectives

• Use the product of a power property.
• Use the power of a product property.
• Simplify expressions involving product properties of exponents.

Introduction

In this chapter, we will discuss exponents and exponential functions. In Lessons 8.1, 8.2 and 8.3, we will be learning about the rules governing exponents. We will start with what the word exponent means.

Consider the area of the square shown right. We know that the area is given by:

\[ \text{Area} = x \times x \]

But we also know that for any rectangle, Area = (width) \( \times \) (height), so we can see that:

\[ x \times x = x^2 \]

Similarly, the volume of the cube is given by:

\[ \text{Volume} = \text{width} \times \text{depth} \times \text{height} = x \times x \times x \]

But we also know that the volume of the cube is given by Volume = \( x^3 \) so clearly

\[ x^3 = x \times x \times x \]

You probably know that the power (the small number to the top right of the \( x \)) tells you how many \( x \)'s to multiply together. In these examples the \( x \) is called the base and the power (or exponent) tells us how many factors of the base there are in the full expression.

\[ x^2 = \underbrace{x \times x}_{2 \text{ factors of } x} \quad x^7 = \underbrace{x \times x \times x \times x \times x \times x \times x}_{7 \text{ factors of } x} \]

\[ x^3 = \underbrace{x \times x \times x}_{3 \text{ factors of } x} \quad x^n = \underbrace{x \times x \times \ldots \times x}_{n \text{ factors of } x} \]
Example 1

Write in exponential form.

(a) $2 \cdot 2$
(b) $(-3)(-3)(-3)$
(c) $y \cdot y \cdot y \cdot y \cdot y$
(d) $(3a)(3a)(3a)(3a)$

Solution

(a) $2 \cdot 2 = 2^2$ because we have 2 factors of 2
(b) $(-3)(-3)(-3) = (-3)^3$ because we have 3 factors of $-3$
(c) $y \cdot y \cdot y \cdot y \cdot y = y^5$ because we have 5 factors of $y$
(d) $(3a)(3a)(3a)(3a) = (3a)^4$ because we have 4 factors of $3a$

When we deal with numbers, we usually just simplify. We’d rather deal with 16 than with $2^4$. However, with variables, we need the exponents, because we’d rather deal with $x^7$ than with $x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x$.

Let’s simplify Example 1 by evaluating the numbers.

Example 2

Simplify.

(a) $2 \cdot 2$
(b) $(-3)(-3)(-3)$
(c) $y \cdot y \cdot y \cdot y \cdot y$
(d) $(3a)(3a)(3a)(3a)$

Solution

(a) $2 \cdot 2 = 2^2 = 4$
(b) $(-3)(-3)(-3) = (-3)^3 = -27$
(c) $y \cdot y \cdot y \cdot y \cdot y = y^5$
(d) $(3a)(3a)(3a)(3a) = (3a)^4 = 3^4 \cdot a^4 = 81a^4$

Note: You must be careful when taking powers of negative numbers. Remember these rules.

(negative number) (positive number) = negative number
(negative number) (negative number) = positive number

For even powers of negative numbers, the answer is always positive. Since we have an even number of factors, we make pairs of negative numbers and all the negatives cancel out.

$$(-2)^6 = (-2)(-2)(-2)(-2)(-2)(-2) = \underbrace{(-2)(-2)}_{+4} \cdot \underbrace{(-2)(-2)}_{+4} \cdot \underbrace{(-2)(-2)}_{+4} = +64$$

For odd powers of negative numbers, the answer is always negative. Since we have an odd number of factors, we can make pairs of negative numbers to get positive numbers but there is always an unpaired negative factor, so the answer is negative:

Ex: $(-2)^5 = (-2)(-2)(-2)(-2)(-2) = \underbrace{(-2)(-2)}_{+4} \cdot \underbrace{(-2)(-2)}_{+4} \cdot \underbrace{(-2)}_{-2} = -32$
Use the Product of Powers Property

What happens when we multiply one power of \( x \) by another? See what happens when we multiply \( x \) to the power 5 by \( x \) cubed. To illustrate better we will use the full factored form for each:

\[
\left( x \cdot x \cdot x \cdot x \cdot x \right) \cdot \left( x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \right) = \left( x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \right)
\]

So \( x^5 \cdot x^3 = x^8 \). You may already see the pattern to multiplying powers, but lets confirm it with another example. We will multiply \( x \) squared by \( x \) to the power 4:

\[
\left( x \cdot x \right) \cdot \left( x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \right) = \left( x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \right)
\]

So \( x^2 \cdot x^4 = x^6 \). Look carefully at the powers and how many factors there are in each calculation. 5 factors of \( x \) times 3 factors of \( x \) equals \((5 + 3) = 8\) factors of \( x \). 2 factors of \( x \) times 4 factors of \( x \) equals \((2 + 4) = 6\) factors of \( x \).

You should see that when we take the product of two powers of \( x \), the number of factors of \( x \) in the answer is the sum of factors in the terms you are multiplying. In other words the exponent of \( x \) in the answer is the sum of the exponents in the product.

Product rule for exponents: \( x^n \cdot x^m = x^{n+m} \)

**Example 3**

Multiply \( x^4 \cdot x^5 \).

**Solution**

\( x^4 \cdot x^5 = x^{4+5} = x^9 \)

When multiplying exponents of the same base, it is a simple case of adding the exponents. It is important that when you use the product rule you avoid easy-to-make mistakes. Consider the following.

**Example 4**

Multiply \( 2^2 \cdot 2^3 \).

**Solution**

\[
2^2 \cdot 2^3 = 2^5 = 32
\]

Note that when you use the product rule you DO NOT MULTIPLY BASES. In other words, you must avoid the common error of writing \( 2^2 \cdot 2^3 = 4^5 \). Try it with your calculator and check which is right!

**Example 5**

Multiply \( 2^2 \cdot 3^3 \).

**Solution**

\[
2^2 \cdot 3^3 = 4 \cdot 27 = 108
\]

In this case, the bases are different. The product rule for powers ONLY APPLIES TO TERMS THAT HAVE THE SAME BASE. Common mistakes with problems like this include \( 2^2 \cdot 3^3 = 6^5 \).
5.1. Exponent Properties Involving Products

Use the Power of a Product Property

We will now look at what happens when we raise a whole expression to a power. Let's take \( x \) to the power 4 and cube it. Again we will use the full factored form for each.

\[
(x^4)^3 = x^4 \cdot x^4 \cdot x^4 \quad \text{3 factors of } x \text{ to the power 4.}
\]

\[
(x \cdot x \cdot x \cdot x) \cdot (x \cdot x \cdot x \cdot x) \cdot (x \cdot x \cdot x \cdot x) = (x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x)_{x^{12}}
\]

So \((x^4)^3 = x^{12}\). It is clear that when we raise a power of \( x \) to a new power, the powers multiply.

When we take an expression and raise it to a power, we are multiplying the existing powers of \( x \) by the power above the parenthesis.

Power rule for exponents: \((x^n)^m = x^{nm}\)

**Power of a product**

If we have a product inside the parenthesis and a power on the parenthesis, then the power goes on each element inside. So that, for example, \((x^2y)^4 = \left((x^2) \cdot (y)^4 = x^8y^4\right)\). Watch how it works the long way.

\[
(x \cdot x \cdot y) \cdot (x \cdot x \cdot y) \cdot (x \cdot x \cdot y) \cdot (x \cdot x \cdot y) = (x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot y \cdot y \cdot y)
\]

Power rule for exponents: \((x^n)^m = x^{nm}\) and \((x^m y^n)^p = x^{np} y^{mp}\)

WATCH OUT! This does NOT work if you have a sum or difference inside the parenthesis. For example, \((x + y)^2 \neq x^2 + y^2\). This is a commonly made mistake. It is easily avoidable if you remember what an exponent means \((x + y)^2 = (x + y)(x + y)\). We will learn how to simplify this expression in a later chapter.

Let's apply the rules we just learned to a few examples.

When we have numbers, we just evaluate and most of the time it is not really important to use the product rule and the power rule.

**Example 6**

Simplify the following expressions.

(a) \(3^4 \cdot 3^7\)

(b) \(2^6 \cdot 2\)

(c) \((4^2)^3\)

**Solution**

In each of the examples, we want to evaluate the numbers.

(a) Use the product rule first: \(3^5 \cdot 3^7 = 3^{12}\)

Then evaluate the result: \(3^{12} = 531,441\)

OR

We can evaluate each part separately and then multiply them. \(3^5 \cdot 3^7 = 243 \cdot 2,187 = 531,441\).
Use the product rule first. $2^6 \cdot 2 = 2^7$
Then evaluate the result. $2^7 = 128$

OR
We can evaluate each part separately and then multiply them. $2^6 \cdot 2 = 64 \cdot 2 = 128$

(c) Use the power rule first. $(4^2)^3 = 4^6$
Then evaluate the result. $4^6 = 4096$

OR
We evaluate inside the parenthesis first. $(4^2)^3 = (16)^3$
Then apply the power outside the parenthesis. $(16)^3 = 4096$

When we have just one variable in the expression then we just apply the rules.

**Example 7**

*Simplify the following expressions.*

(a) $x^2 \cdot x^7$

(b) $(y^3)^5$

**Solution**

(a) Use the product rule. $x^2 \cdot x^7 = x^{2+7} = x^9$

(b) Use the power rule. $(y^3)^5 = y^{3 \cdot 5} = y^{15}$

When we have a mix of numbers and variables, we apply the rules to the numbers or to each variable separately.

**Example 8**

*Simplify the following expressions.*

(a) $(3x^2y^3) \cdot (4xy^2)$

(b) $(4xyz) \cdot (x^2y^3) \cdot (2yz^4)$

(c) $(2a^3b^3)^2$

**Solution**

(a) We group like terms together.

$$(3x^2y^3) \cdot (4xy^2) = (3 \cdot 4) \cdot (x^2 \cdot x) \cdot (y^3 \cdot y^2)$$

We multiply the numbers and apply the product rule on each grouping.

$$12x^3y^5$$

(b) We groups like terms together.

$$(4xyz) \cdot (x^2y^3) \cdot (2yz^4) = (4 \cdot 2) \cdot (x \cdot x^2) \cdot (y \cdot y^3 \cdot y) \cdot (z \cdot z^4)$$

We multiply the numbers and apply the product rule on each grouping.
5.1. Exponent Properties Involving Products

\[ 8x^3y^5z^5 \]

(c) We apply the power rule for each separate term in the parenthesis.

\[ (2a^3b^3)^2 = 2^2 \cdot (a^3)^2 \cdot (b^3)^2 \]

We evaluate the numbers and apply the power rule for each term.

\[ 4a^6b^6 \]

In problems that we need to apply the product and power rules together, we must keep in mind the order of operation. Exponent operations take precedence over multiplication.

**Example 9**

*Simplify the following expressions.*

(a) \((x^2)^2 \cdot x^3\)

(b) \((2x^2y) \cdot (3xy)^3\)

(c) \((4a^2b^3)^2 \cdot (2ab^4)^3\)

**Solution**

(a) \((x^2)^2 \cdot x^3\)

We apply the power rule first on the first parenthesis.

\[(x^2)^2 \cdot x^3 = x^4 \cdot x^3\]

Then apply the product rule to combine the two terms.

\[x^4 \cdot x^3 = x^7\]

(b) \((2x^2y) \cdot (3xy)^3\)

We must apply the power rule on the second parenthesis first.

\[(2x^2y) \cdot (3xy)^3 = (2x^2y) \cdot (27x^3y^6)\]

Then we can apply the product rule to combine the two parentheses.

\[(2x^2y) \cdot (27x^3y^6) = 54x^5y^7\]

(c) \((4a^2b^3)^2 \cdot (2ab^4)^3\)
We apply the power rule on each of the parentheses separately.

\[(4a^2b^3)^2 \cdot (2ab^4)^3 = (16a^4b^6) \cdot (8a^3b^{12})\]

Then we can apply the product rule to combine the two parentheses.

\[(16a^4b^6) \cdot (8a^3b^{12}) = 128a^7b^{18}\]
5.2 Exponent Properties Involving Quotients

Learning Objectives

- Use the quotient of powers property.
- Use the power of a quotient property.
- Simplify expressions involving quotient properties of exponents.

Use the Quotient of Powers Property

You saw in the last section that we can use exponent rules to simplify products of numbers and variables. In this section, you will learn that there are similar rules you can use to simplify quotients. Let’s take an example of a quotient, \( \frac{x^7}{x^4} \).

\[
\frac{x^7}{x^4} = \frac{x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x}{x \cdot x \cdot x} = \frac{x \cdot x \cdot x}{1} = x^3
\]

You should see that when we divide two powers of \( x \), the number of factors of \( x \) in the solution is the difference between the factors in the numerator of the fraction, and the factors in the denominator. In other words, when dividing expressions with the same base, keep the base and subtract the exponent in the denominator from the exponent in the numerator.

**Quotient Rule for Exponents:** \( \frac{x^n}{x^m} = x^{n-m} \)

When we have problems with different bases, we apply the quotient rule separately for each base.

\[
\frac{x^5 y^3}{x^3 y^2} = \frac{x \cdot x \cdot x \cdot x \cdot x}{x \cdot x \cdot x} \cdot \frac{y \cdot y \cdot y}{y \cdot y} = \frac{x}{1} \cdot \frac{y}{1} = x^2 y \quad \text{OR} \quad \frac{x^5 y^3}{x^3 y^2} = x^{5-3} \cdot y^{3-2} = x^2 y
\]

**Example 1**

Simplify each of the following expressions using the quotient rule.

(a) \( \frac{x^{10}}{x^5} \)

(b) \( \frac{a^6}{a} \)

(c) \( \frac{a^5 b^4}{a^3 b^2} \)

**Solution**

**Apply the quotient rule.**

(a) \( \frac{x^{10}}{x^5} = x^{10-5} = x^5 \)

(b) \( \frac{a^6}{a} = a^{6-1} = a^5 \)

(c) \( \frac{a^5 b^4}{a^3 b^2} = a^{5-3} \cdot b^{4-2} = a^2 b^2 \)

Now let’s see what happens if the exponent on the denominator is bigger than the exponent in the numerator.
**Example 2**

Divide. $x^4 \div x^7$

\[
\frac{x^4}{x^7} = x^{4-7} = x^{-3}
\]

A negative exponent!? What does that mean?

Let’s do the division longhand by writing each term in factored form.

\[
\frac{x^4}{x^6} = \frac{x \cdot x \cdot x \cdot x}{x \cdot x \cdot x \cdot x \cdot x} = \frac{1}{x^2}
\]

We see that when the exponent in the denominator is bigger than the exponent in the numerator, we still subtract the powers. This time we subtract the smaller power from the bigger power and we leave the $x$’s in the denominator.

When you simplify quotients, to get answers with positive exponents you subtract the smaller exponent from the bigger exponent and leave the variable where the bigger power was.

- We also discovered what a negative power means $x^{-3} = \frac{1}{x^3}$. We’ll learn more on this in the next section!

**Example 3**

Simplify the following expressions, leaving all powers positive.

(a) $\frac{x^2}{x^6}$

(b) $\frac{a^2b}{a^5b}$

**Solution**

(a) Subtract the exponent in the numerator from the exponent in the denominator and leave the $x$’s in the denominator.

\[
\frac{x^2}{x^6} = \frac{1}{x^{6-2}} = \frac{1}{x^4}
\]

(b) Apply the rule on each variable separately.

\[
\frac{a^2b^6}{a^5b} = \frac{1}{a^{5-2}} \cdot \frac{b^{6-1}}{1} = \frac{b^5}{a^3}
\]

**The Power of a Quotient Property**

When we apply a power to a quotient, we can learn another special rule. Here is an example.

\[
\left(\frac{x^3}{y^2}\right)^4 = \left(\frac{x^3}{y^2}\right) \cdot \left(\frac{x^3}{y^2}\right) \cdot \left(\frac{x^3}{y^2}\right) \cdot \left(\frac{x^3}{y^2}\right) = \frac{(x \cdot x \cdot x) \cdot (x \cdot x \cdot x) \cdot (x \cdot x \cdot x) \cdot (x \cdot x \cdot x)}{(y \cdot y) \cdot (y \cdot y) \cdot (y \cdot y) \cdot (y \cdot y)} = \frac{x^{12}}{y^8}
\]

Notice that the power on the outside of the parenthesis multiplies with the power of the $x$ in the numerator and the power of the $y$ in the denominator. This is called the power of a quotient rule.

Power Rule for Quotients $\left(\frac{x^a}{y^b}\right)^p = \frac{x^{ap}}{y^{bp}}$
### Simplifying Expressions Involving Quotient Properties of Exponents

Let's apply the rules we just learned to a few examples.

- When we have numbers with exponents and not variables with exponents, we evaluate.

**Example 4**

*Simplify the following expressions.*

(a) \( \frac{4^5}{4^2} \)

(b) \( \frac{5^5}{5^7} \)

(c) \( \left( \frac{3^4}{5^2} \right)^2 \)

**Solution**

In each of the examples, we want to evaluate the numbers.

(a) Use the quotient rule first.

\[
\frac{4^5}{4^2} = 4^{5-2} = 4^3
\]

Then evaluate the result.

\[4^3 = 64\]

OR

We can evaluate each part separately and then divide.

\[
\frac{1024}{16} = 64
\]

(b) Use the quotient rule first.

\[
\frac{5^3}{5^7} = \frac{1}{5^{7-3}} = \frac{1}{5^4}
\]

Then evaluate the result.

\[\frac{1}{5^4} = \frac{1}{625}\]

OR

We can evaluate each part separately and then reduce.

\[
\frac{5^3}{5^7} = \frac{125}{78125} = \frac{1}{625}
\]
It makes more sense to apply the quotient rule first for examples (a) and (b). In this way the numbers we are evaluating are smaller because they are simplified first before applying the power.

(c) Use the power rule for quotients first.

\[
\left( \frac{3^4}{5^2} \right)^2 = \frac{3^8}{5^4}
\]

Then evaluate the result.

\[
\frac{3^8}{5^4} = \frac{6561}{625}
\]

OR

We evaluate inside the parenthesis first.

\[
\left( \frac{3^4}{5^2} \right)^2 = \left( \frac{81}{25} \right)^2
\]

Then apply the power outside the parenthesis.

\[
\left( \frac{81}{25} \right)^2 = \frac{6561}{625}
\]

When we have just one variable in the expression, then we apply the rules straightforwardly.

**Example 5:** Simplify the following expressions:

(a) \( \frac{x^{12}}{x^{5}} \)

(b) \( \left( \frac{x^{4}}{x} \right)^{5} \)

**Solution:**

(a) Use the quotient rule.

\[
\frac{x^{12}}{x^{5}} = x^{12-5} = x^{7}
\]

(b) Use the power rule for quotients first.

\[
\left( \frac{x^{4}}{x} \right)^{5} = \frac{x^{20}}{x^{5}}
\]

Then apply the quotient rule

\[
\frac{x^{20}}{x^{5}} = x^{15}
\]
5.2. Exponent Properties Involving Quotients

OR

Use the quotient rule inside the parenthesis first.

\[
\left( \frac{x^4}{x} \right)^5 = (x^3)^5
\]

Then apply the power rule.

\[
(x^3)^5 = x^{15}
\]

When we have a mix of numbers and variables, we apply the rules to each number or each variable separately.

**Example 6**

Simplify the following expressions.

(a) \( \frac{6x^2y^3}{2xy^2} \)

(b) \( \left( \frac{2a^3b^3}{8a^3b} \right)^2 \)

**Solution**

(a) We group like terms together.

\[
\frac{6x^2y^3}{2xy^2} = \frac{6}{2} \cdot \frac{x^2}{x} \cdot \frac{y^3}{y^2}
\]

We reduce the numbers and apply the quotient rule on each grouping.

\[
3xy
\]

(b) We apply the quotient rule inside the parenthesis first.

\[
\left( \frac{2a^3b^3}{8a^3b} \right)^2 = \left( \frac{b^2}{4a^4} \right)^2
\]

Apply the power rule for quotients.

\[
\left( \frac{b^2}{4a^4} \right)^2 = \frac{b^4}{16a^8}
\]

In problems that we need to apply several rules together, we must keep in mind the order of operations.

**Example 7**

Simplify the following expressions.

(a) \( (x^2)^2 \cdot \frac{x^6}{x^3} \)

188
(b) \( \left( \frac{16a^2}{4b^5} \right)^3 \cdot \frac{b^2}{a^{16}} \)

Solution

(a) We apply the power rule first on the first parenthesis.

\[
\left( x^2 \right)^2 \cdot \frac{x^6}{x^4} = x^4 \cdot \frac{x^6}{x^4}
\]

Then apply the quotient rule to simplify the fraction.

\[
x^4 \cdot \frac{x^6}{x^4} = x^4 \cdot x^2
\]

Apply the product rule to simplify.

\[
x^4 \cdot x^2 = x^6
\]

(b) Simplify inside the first parenthesis by reducing the numbers.

\[
\left( \frac{4a^2}{b^5} \right)^3 \cdot \frac{b^2}{a^{16}}
\]

Then we can apply the power rule on the first parenthesis.

\[
\left( \frac{4a^2}{b^5} \right)^3 \cdot \frac{b^2}{a^{16}} = 64a^6 \cdot \frac{b^2}{b^{15}}
\]

Group like terms together.

\[
64a^6 \cdot \frac{b^2}{b^{15}} = 64 \cdot \frac{a^6}{a^{16}} \cdot \frac{b^2}{b^{15}}
\]

Apply the quotient rule on each fraction.

\[
64 \cdot \frac{a^6}{a^{16}} \cdot \frac{b^2}{b^{15}} = 64 \cdot \frac{a^{10}b^{13}}{a^{10}b^{13}}
\]
5.3 Zero, Negative, and Fractional Exponents

Learning Objectives

- Simplify expressions with zero exponents.
- Simplify expressions with negative exponents.
- Simplify expression with fractional exponents.
- Evaluate exponential expressions.

Introduction

There are many interesting concepts that arise when contemplating the product and quotient rule for exponents. You may have already been wondering about different values for the exponents. For example, so far we have only considered positive, whole numbers for the exponent. So called natural numbers (or counting numbers) are easy to consider, but even with the everyday things around us we think about questions such as is it possible to have a negative amount of money? or what would one and a half pairs of shoes look like? In this lesson, we consider what happens when the exponent is not a natural number. We will start with What happens when the exponent is zero?

Simplify Expressions with Exponents of Zero

Let us look again at the quotient rule for exponents (that $\frac{x^n}{x^m} = x^{n-m}$) and consider what happens when $n = m$. Let’s take the example of $x^4$ divided by $x^4$.

$$\frac{x^4}{x^4} = x^{4-4} = x^0$$

Now we arrived at the quotient rule by considering how the factors of $x$ cancel in such a fraction. Let’s do that again with our example of $x^4$ divided by $x^4$.

$$\frac{x^4}{x^4} = \frac{x \cdot x \cdot x \cdot x}{x \cdot x \cdot x} = 1$$

So $x^0 = 1$.

This works for any value of the exponent, not just 4.

$$\frac{x^n}{x^m} = x^{n-m} = x^0$$

Since there is the same number of factors in the numerator as in the denominator, they cancel each other out and we obtain $x^0 = 1$. The zero exponent rule says that any number raised to the power zero is one.

Zero Rule for Exponents: $x^0 = 1$, $x \neq 0$
Simplify Expressions With Negative Exponents

Again we will look at the quotient rule for exponents (that \( \frac{x^m}{x^n} = x^{m-n} \)) and this time consider what happens when \( m > n \). Let’s take the example of \( x^4 \) divided by \( x^6 \).

\[
\frac{x^4}{x^6} = x^{(4-6)} = x^{-2} \text{ for } x \neq 0.
\]

By the quotient rule our exponent for \( x \) is \(-2\). But what does a negative exponent really mean? Let’s do the same calculation long-hand by dividing the factors of \( x^4 \) by the factors of \( x^6 \).

\[
\frac{x^4}{x^6} = \frac{x \cdot x \cdot x \cdot x}{x \cdot x \cdot x \cdot x \cdot x \cdot x} = \frac{1}{x \cdot x} = \frac{1}{x^2}
\]

So we see that \( x \) to the power \(-2\) is the same as one divided by \( x \) to the power +2. Here is the negative power rule for exponents.

**Negative Power Rule for Exponents**

\[
\frac{1}{x^n} = x^{-n} \quad x \neq 0
\]

You will also see negative powers applied to products and fractions. For example, here it is applied to a product.

\[
(x^3y)^{-2} = x^{-6}y^{-2} \quad \text{using the power rule}
\]

\[
x^{-6}y^{-2} = \frac{1}{x^6} \cdot \frac{1}{y^2} = \frac{1}{x^6y^2} \quad \text{using the negative power rule separately on each variable}
\]

Here is an example of a negative power applied to a quotient.

\[
\left(\frac{a}{b}\right)^{-3} = \frac{a^{-3}}{b^{-3}} \quad \text{using the power rule for quotients}
\]

\[
a^{-3} = \frac{a^{-3}}{1} \cdot \frac{1}{b^{-3}} = \frac{1}{a^3} \cdot \frac{b^3}{1} \quad \text{using the negative power rule on each variable separately}
\]

\[
\frac{1}{a^3} \cdot \frac{b^3}{1} = \frac{b^3}{a^3} \quad \text{simplifying the division of fractions}
\]

\[
\frac{b^3}{a^3} = \left(\frac{b}{a}\right)^3 \quad \text{using the power rule for quotients in reverse.}
\]

The last step is not necessary but it helps define another rule that will save us time. A fraction to a negative power is flipped.

**Negative Power Rule for Fractions**

\[
\left(\frac{a}{b}\right)^{-n} = \left(\frac{b}{a}\right)^n, \quad x \neq 0, y \neq 0
\]

In some instances, it is more useful to write expressions without fractions and that makes use of negative powers.

**Example 1**

Write the following expressions without fractions.

(a) \( \frac{1}{x} \)

(b) \( \frac{2}{x} \)

(c) \( \frac{x^2}{y} \)

(d) \( \frac{3}{xy} \)

**Solution**
We apply the negative rule for exponents \( \frac{1}{x^n} = x^{-n} \) on all the terms in the denominator of the fractions.

(a) \( \frac{1}{x} = x^{-1} \)
(b) \( \frac{2}{x^2} = 2x^{-2} \)
(c) \( \frac{x}{y^3} = x^2y^{-3} \)
(d) \( \frac{3}{xy} = 3x^{-1}y^{-1} \)

Sometimes, it is more useful to write expressions without negative exponents.

**Example 2**

*Write the following expressions without negative exponents.*

(a) \( 3x^{-3} \)
(b) \( a^2b^{-3}c^{-1} \)
(c) \( 4x^{-1}y^3 \)
(d) \( \frac{2x^{-2}}{y^{-3}} \)

**Solution**

We apply the negative rule for exponents \( \frac{1}{x^n} = x^{-n} \) on all the terms that have negative exponents.

(a) \( 3x^{-3} = \frac{3}{x^3} \)
(b) \( a^2b^{-3}c^{-1} = \frac{a^2}{b^3c} \)
(c) \( 4x^{-1}y^3 = \frac{4y^3}{x} \)
(d) \( \frac{2x^{-2}}{y^{-3}} = \frac{2y^3}{x^2} \)

**Example 3**

*Simplify the following expressions and write them without fractions.*

(a) \( \frac{4a^2b^3}{2a^3b} \)
(b) \( \left(\frac{x}{3y^2}\right)^3 \cdot \frac{2x^3}{4} \)

**Solution**

(a) Reduce the numbers and apply quotient rule on each variable separately.

\[
\frac{4a^2b^3}{6a^3b} = 2 \cdot a^{2-3} \cdot b^{3-1} = 2a^{-1}b^2
\]

(b) Apply the power rule for quotients first.

\[
\left(\frac{2x}{y^2}\right)^3 \cdot \frac{x^2y}{4} = \frac{8x^3}{y^6} \cdot \frac{x^2y}{4}
\]

Then simplify the numbers, use product rule on the \( x \)'s and the quotient rule on the \( y \)'s.

\[
\frac{8x^3}{y^6} \cdot \frac{x^2y}{4} = 2 \cdot x^{3+2} \cdot y^{1-6} = 2x^5y^{-5}
\]

192
Example 4

Simplify the following expressions and write the answers without negative powers.

(a) \((ab^{-2})^2\)

Solution

(a) Apply the quotient rule inside the parenthesis.

\[
(ab^{-2})^2 = (ab^{-5})^2
\]

Apply the power rule.

\[
(ab^{-5})^2 = a^2 b^{-10} = \frac{a^2}{b^{10}}
\]

(b) Apply the quotient rule on each variable separately.

\[
\frac{x^{-3}y^2}{x^2y^{-2}} = x^{-3-2}y^{2-(-2)} = x^{-5}y^4 = \frac{y^4}{x^5}
\]

Simplify Expressions With Fractional Exponents

The exponent rules you learned in the last three sections apply to all powers. So far we have only looked at positive and negative integers. The rules work exactly the same if the powers are fractions or irrational numbers. Fractional exponents are used to express the taking of roots and radicals of something (square roots, cube roots, etc.). Here is an example.

\[
\sqrt{a} = a^{1/2} \quad \text{and} \quad \sqrt[3]{a} = a^{1/3} \quad \text{and} \quad \sqrt[n]{a} = (a^2)^{\frac{1}{n}} = a^{2/n}
\]

Roots as Fractional Exponents \(\sqrt[n]{a^m} = a^{m/n}\)

We will examine roots and radicals in detail in a later chapter. In this section, we will examine how exponent rules apply to fractional exponents.

Evaluate Exponential Expressions

When evaluating expressions we must keep in mind the order of operations. You must remember PEMDAS.

Evaluate inside the Parenthesis.

Evaluate Exponents.

Perform Multiplication and Division operations from left to right.

Perform Addition and Subtraction operations from left to right.

Example 6

Evaluate the following expressions to a single number.

(a) \(5^0\)

(b) \(7^2\)
5.3. Zero, Negative, and Fractional Exponents

Solution

(a) $5^0 = 1$ Remember that a number raised to the power 0 is always 1.
(b) $7^2 = 7 \cdot 7 = 49$
(c) $(\frac{2}{3})^3 = \frac{2^3}{3^3} = \frac{8}{27}$
(d) $3^{-3} = \frac{1}{3^3} = \frac{1}{27}$

Example 7

Evaluate the following expressions to a single number.

(a) $3 \cdot 5^2 - 10 \cdot 5 + 1$
(b) $\frac{2 \cdot 4^2 - 3 \cdot 5^2}{3^2}$
(c) $\left( \frac{3^7}{2^7} \right)^2 \cdot \frac{3}{4}$

Solution

(a) Evaluate the exponent.

$$3 \cdot 5^2 - 10 \cdot 5 + 1 = 3 \cdot 25 - 10 \cdot 5 + 1$$

Perform multiplications from left to right.

$$3 \cdot 25 - 10 \cdot 5 + 1 = 75 - 50 + 1$$

Perform additions and subtractions from left to right.

$$75 - 50 + 1 = 26$$

(b) Treat the expressions in the numerator and denominator of the fraction like they are in parenthesis.

$$\frac{2 \cdot 4^2 - 3 \cdot 5^2}{3^2} = \frac{2 \cdot 16 - 3 \cdot 25}{9} = \frac{32 - 75}{9} = \frac{-43}{9}$$

(c) $\left( \frac{3^7}{2^7} \right)^2 \cdot \frac{3}{4} = \left( \frac{3^7}{2^7} \right)^2 \cdot \frac{3}{4} = \frac{27^2}{2^7} \cdot \frac{3}{4} = \frac{27^2}{2^7} \cdot \frac{3}{4} = \frac{4}{243}$

Example 8

Evaluate the following expressions for $x = 2, y = -1, z = 3$.

(a) $2x^2 - 3y^3 + 4z$
(b) $(x^2 - y^2)^2$
(c) $\left( \frac{3x^2y^3}{4z} \right)^{-2}$

Solution

194
www.ck12.org

Chapter 5. Exponential Functions

(a) \(2x^2 - 3y^4 + 4z = 2 \cdot 2^2 - 3 \cdot (-1)^3 + 4 \cdot 3 = 2 \cdot 4 - 3 \cdot (-1) + 4 \cdot 3 = 8 + 3 + 12 = 23\)

(b) \((x^2 - y^2)^2 = (2^2 - (-1)^2)^2 = (4 - 1)^2 = 3^2 = 9\)

(c) \(\left(\frac{3x^2 - y^3}{4z}\right)^{-2} = \left(\frac{3 \cdot 2^2 - (-1)^3}{4 \cdot 3}\right)^{-2} = \left(\frac{3 \cdot 4 - (-1)}{12}\right)^{-2} = \left(\frac{-12}{12}\right)^{-2} = \left(\frac{-1}{1}\right)^{-2} = \left(\frac{-1}{-1}\right)^2 = (-1)^2 = 1\)
5.4 Scientific Notation

Learning Objectives

- Write numbers in scientific notation.
- Evaluate expressions in scientific notation.
- Evaluate expressions in scientific notation using a graphing calculator.

Introduction Powers of 10

Consider the number six hundred and forty three thousand, two hundred and ninety seven. We write it as 643,297 and each digits position has a value assigned to it. You may have seen a table like this before.

<table>
<thead>
<tr>
<th>hundred-thousands</th>
<th>ten-thousands</th>
<th>thousands</th>
<th>hundreds</th>
<th>tens</th>
<th>units (ones)</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>9</td>
<td>7</td>
</tr>
</tbody>
</table>

We have seen that when we write an exponent above a number it means that we have to multiply a certain number of factors of that number together. We have also seen that a zero exponent always gives us one, and negative exponents make fractional answers. Look carefully at the table above. Do you notice that all the column headings are powers of ten? Here they are listed.

\[
\begin{align*}
100,000 &= 10^5 \\
10,000 &= 10^4 \\
1,000 &= 10^3 \\
100 &= 10^2 \\
10 &= 10^1
\end{align*}
\]

Even the units column is really just a power of ten. Unit means 1 and \(1 = 10^0\).

If we divide 643,297 by 100,000 we get 6.43297. If we multiply this by 100,000 we get back to our original number. But we have just seen that 100,000 is the same as \(10^5\), so if we multiply 6.43297 by \(10^5\) we should also get our original answer. In other words

\[
6.43297 \times 10^5 = 643,297
\]

So we have found a new way of writing numbers! What do you think happens when we continue the powers of ten? Past the units column down to zero we get into decimals, here the exponent becomes negative.

Writing Numbers Greater Than One in Scientific Notation

Scientific notation numbers are always written in the following form.
Where \( 1 \leq a < 10 \) and \( b \), the exponent, is an integer. This notation is especially useful for numbers that are either very small or very large. When we use scientific notation to write numbers, the exponent on the 10 determines the position of the decimal point.

Look at the following examples.

\[
1.07 \times 10^4 = 10,700 \\
1.07 \times 10^3 = 1,070 \\
1.07 \times 10^2 = 107 \\
1.07 \times 10^1 = 10.7 \\
1.07 \times 10^0 = 1.07 \\
1.07 \times 10^{-1} = 0.107 \\
1.07 \times 10^{-2} = 0.0107 \\
1.07 \times 10^{-3} = 0.00107 \\
1.07 \times 10^{-4} = 0.000107
\]

Look at the first term of the list and examine the position of the decimal point in both expressions.

So the exponent on the ten acts to move the decimal point over to the right. An exponent of 4 moves it 4 places and an exponent of 3 would move it 3 places.

Example 1

Write the following numbers in scientific notation.

(a) 63
(b) 9,654
(c) 653,937,000
5.4. Scientific Notation

(d) $1,000,000,006$
(a) $63 = 6.3 \times 10 = 6.3 \times 10^1$
(b) $9,654 = 9.654 \times 1,000 = 9.654 \times 10^3$
(c) $653,937,000 = 6.53937000 \times 100,000,000 = 6.53937 \times 10^8$
(d) $1,000,000,006 = 1.000000006 \times 1,000,000,000 = 1.000000006 \times 10^9$

Example 2
*The Sun is approximately 93 million miles for Earth. Write this distance in scientific notation.*

This time we will simply write out the number long-hand (with a decimal point) and count decimal places.

**Solution**

$$93,000,000,0 = 9.3 \times 10^7 	ext{ miles}$$

**7 decimal places**

A Note on Significant Figures

We often combine scientific notation with rounding numbers. If you look at Example 2, the distance you are given has been rounded. It is unlikely that the distance is exactly 93 million miles! Looking back at the numbers in Example 1, if we round the final two answers to 2 significant figures (2 s.f.) they become:

1(c) $6.5 \times 10^8$
1(d) $1.0 \times 10^9$

Note that the zero after the decimal point has been left in for Example 1(d) to indicate that the result has been rounded. It is important to know when it is OK to round and when it is not.

Writing Numbers Less Than One in Scientific Notation

We have seen how we can use scientific notation to express large numbers, but it is equally good at expressing extremely small numbers. Consider the following example.

Example 3
*The time taken for a light beam to cross a football pitch is 0.0000004 seconds. Express this time in scientific notation.*

We will proceed in a similar way as before.

$$0.0000004 = 4 \times 0.0000001 = 4 \times \frac{1}{10,000,000} = 4 \times \frac{1}{10^7} = 4 \times 10^{-7}$$

So...

$$4 \times 10^{-7} = 0.0000004$$

Just as a positive exponent on the ten moves the decimal point that many places to the right, a negative exponent moves the decimal place that many places to the left.
Example 4

Express the following numbers in scientific notation.

(a) 0.003
(b) 0.000056
(c) 0.00005007
(d) 0.0000000000954

Let's use the method of counting how many places we would move the decimal point before it is after the first non-zero number. This will give us the value for our negative exponent.

(a) $0.003 = 3 \times 10^{-3}$

(b) $0.000056 = 5.6 \times 10^{-5}$

(c) $0.00005007 = 5.007 \times 10^{-5}$

(d) $0.0000000000954 = 9.54 \times 10^{-12}$

Evaluating Expressions in Scientific Notation

When we are faced with products and quotients involving scientific notation, we need to remember the rules for exponents that we learned earlier. It is relatively straightforward to work with scientific notation problems if you remember to deal with all the powers of 10 together. The following examples illustrate this.

Example 5

Evaluate the following expressions and write your answer in scientific notation.

(a) $(3.2 \times 10^6) \cdot (8.7 \times 10^{11})$

(b) $(5.2 \times 10^{-4}) \cdot (3.8 \times 10^{-19})$

(c) $(1.7 \times 10^6) \cdot (2.7 \times 10^{-11})$

The key to evaluating expressions involving scientific notation is to keep the powers of 10 together and deal with them separately. Remember that when we use scientific notation, the leading number must be between 1 and 10. We need to move the decimal point over one place to the left. See how this adds 1 to the exponent on the 10.

(a) 

$$(3.2 \times 10^6) \cdot (8.7 \times 10^{11}) = 3.2 \times 8.7 \times 10^6 \times 10^{11} = 27.84 \times 10^{17} = 2.784 \times 10^{18}$$

Solution

$$(3.2 \times 10^6) \cdot (8.7 \times 10^{11}) = 2.784 \times 10^{18}$$
\[(5.2 \times 10^{-4}) \cdot (3.8 \times 10^{-19}) = \frac{5.2 \times 3.8}{19.76} \times 10^{-4} \times 10^{-19} = 1.976 \times 10^{-23}\]

Solution

\[(5.2 \times 10^{-4}) \cdot (3.8 \times 10^{-19}) = 1.976 \times 10^{-22}\]

(c)

\[(1.7 \times 10^6) \cdot (2.7 \times 10^{-11}) = \frac{1.7 \times 2.7 \times 10^6 \times 10^{-11}}{4.59 \times 10^{-5}}\]

Solution

\[(1.7 \times 10^6) \cdot (2.7 \times 10^{-11}) = 4.59 \times 10^{-5}\]

Example 6

Evaluate the following expressions. Round to 3 significant figures and write your answer in scientific notation.

(a) \((3.2 \times 10^6) \div (8.7 \times 10^{11})\)

(b) \((5.2 \times 10^{-4}) \div (3.8 \times 10^{-19})\)

(c) \((1.7 \times 10^6) \div (2.7 \times 10^{-11})\)

It will be easier if we convert to fractions and THEN separate out the powers of 10.

(a)

\[(3.2 \times 10^6) \div (8.7 \times 10^{11}) = \frac{3.2 \times 10^6}{8.7 \times 10^{11}} = \frac{3.2}{8.7} \times \frac{10^6}{10^{11}} = 0.368 \times 10(6 - 11) = 3.68 \times 10^{-1} \times 10^{-5}\]

Solution

\((3.2 \times 10^6) \div (8.7 \times 10^{11}) = 3.86 \times 10^{-6} \text{ (rounded to 3 significant figures)}\)

(b)

\[(5.2 \times 10^{-4}) \div (3.8 \times 10^{19}) = \frac{5.2 \times 10^{-4}}{3.8 \times 10^{-19}} = \frac{5.2}{3.8} \times \frac{10^{-4}}{10^{-19}} = 1.37 \times 10(( -4) - (-19)) = 1.37 \times 10^{15}\]

Separate the powers of 10.

Evaluate each fraction (round to 3 s.f.).
Solution

\[(5.2 \times 10^{-4}) ÷ (3.8 \times 10^{-19}) = 1.37 \times 10^{15} \text{ (rounded to 3 significant figures)}\]

(c)

\[
(1.7 \times 10^6) ÷ (2.7 \times 10^{-11}) = \frac{1.7 \times 10^6}{2.7 \times 10^{-11}}
\]

\[
= \frac{1.7}{2.7} \times 10^{6+11}
\]

\[
= 0.630 \times 10^{(6-(-11))}
\]

\[
= 6.30 \times 10^1 \times 10^{17}
\]

Next we separate the powers of 10.

Evaluate each fraction (round to 3 s.f.).

Remember how to write scientific notation!

Solution

\[(1.7 \times 10^6) ÷ (2.7 \times 10^{-11}) = 6.30 \times 10^{16} \text{ (rounded to 3 significant figures)}\]

Note that the final zero has been left in to indicate that the result has been rounded.

Evaluate Expressions in Scientific Notation Using a Graphing Calculator

All scientific and graphing calculators have the ability to use scientific notation. It is extremely useful to know how to use this function.

To insert a number in scientific notation, use the [EE] button. This is [2nd] [,] on some TI models.

For example to enter \(2.6 \times 10^5\) enter 2.6 [EE] 5.

When you hit [ENTER] the calculator displays 2.6E5 if its set in Scientific mode OR it displays 260000 if its set in Normal mode.

(To change the mode, press the Mode key)

Example 7

Evaluate \((1.7 \times 10^6) ÷ (2.7 \times 10^{-11})\) using a graphing calculator.

[ENTER] 1.7 EE 6 ÷ 2.7 EE -11 and press [ENTER]
The calculator displays $6.296296296E16$ whether it is in Normal mode or Scientific mode. This is the case because the number is so big that it does not fit inside the screen in Normal mode.

**Solution**

$$(1.7 \times 10^6) ÷ (2.7 \times 10^{-11}) = 6.3 \times 10^{16}$$

**Example 8**

*Evaluate $(2.3 \times 10^6) \times (4.9 \times 10^{-10})$ using a graphing calculator.*

[ENTER] $2.3 \times 10^6 \times 4.9 \times 10^{-10}$ and press [ENTER]

The calculator displays .001127 in Normal mode or $1.127E - 3$ in Scientific mode.

**Solution**

$$(2.3 \times 10^6) \times (4.9 \times 10^{-10}) = 1.127 \times 10^{-3}$$

**Example 9**

*Evaluate $(4.5 \times 10^{14})^3$ using a graphing calculator.*

[ENTER] $(4.5\times 10^{14})^3$ and press [ENTER].
The calculator displays $9.1125 \times 10^{43}$

Solution

$$(4.5 \times 10^{14})^3 = 9.1125 \times 10^{43}$$

Solve Real-World Problems Using Scientific Notation

Example 10

*The mass of a single lithium atom is approximately one percent of one millionth of one billionth of one billionth of one kilogram. Express this mass in scientific notation.*

We know that percent means we divide by 100, and so our calculation for the mass (in kg) is

$$\frac{1}{100} \times \frac{1}{1,000,000} \times \frac{1}{1,000,000,000} \times \frac{1}{1,000,000,000} = 10^{-2} \times 10^{-6} \times 10^{-9} \times 10^{-9} \times 10^{-9}$$

Next, we use the product of powers rule we learned earlier in the chapter.

$$10^{-2} \times 10^{-6} \times 10^{-9} \times 10^{-9} = 10^{(-2)+(-6)+(-9)+(-9)} = 10^{-26} \text{ kg.}$$

Solution

The mass of one lithium atom is approximately $1 \times 10^{-26}$ kg.

Example 11

*You could fit about 3 million E. coli bacteria on the head of a pin. If the size of the pin head in question is $1.2 \times 10^{-5}$ m², calculate the area taken up by one E. coli bacterium. Express your answer in scientific notation.*

Since we need our answer in scientific notation it makes sense to convert 3 million to that format first:

$$3,000,000 = 3 \times 10^6$$

Next, we need an expression involving our unknown. The area taken by one bacterium. Call this $A$. 
Since 3 million of them make up the area of the pin-head.

Isolate $A$:

$A = \frac{1}{3 \times 10^6} \cdot 1.2 \times 10^{-5}$

Rearranging the terms gives

$A = \frac{1.2}{3} \times \frac{1}{10^6} \times 10^{-5}$

Then using the definition of a negative exponent

$A = \frac{1.2}{3} \times 10^{-6} \times 10^{-5}$

Evaluate combine exponents using the product rule.

$A = 0.4 \times 10^{-11}$

We cannot, however, leave our answer like this.

**Solution**

The area of one bacterium $A = 4.0 \times 10^{-12}$ m$^2$

Notice that we had to move the decimal point over one place to the right, subtracting 1 from the exponent on the 10.
5.5 Exponential Functions

Learning objectives

- Evaluate exponential expressions
- Identify the domain and range of exponential functions
- Graph exponential functions by hand and using a graphing utility
- Solve basic exponential equations

Introduction

In this lesson you will learn about exponential functions, a family of functions we have not studied in prior chapters. In terms of the form of the equation, exponential functions are different from the other function families because the variable $x$ is in the exponent. For example, the functions $f(x) = 2^x$ and $g(x) = 100(2)^x$ are exponential functions. This kind of function can be used to model real situations, such as population growth, compound interest, or the decay of radioactive materials. In this lesson we will look at basic examples of these functions, and we will graph and solve exponential equations. This introduction to exponential functions will prepare you to study applications of exponential functions later in this chapter.

Evaluating Exponential Functions

Consider the function $f(x) = 2^x$. When we input a value for $x$, we find the function value by raising 2 to the exponent of $x$. For example, if $x = 3$, we have $f(3) = 2^3 = 8$. If we choose larger values of $x$, we will get larger function values, as the function values will be larger powers of 2. For example, $f(10) = 2^{10} = 1,024$.

Now let’s consider smaller $x$ values. If $x = 0$, we have $f(0) = 2^0 = 1$. If $x = -3$, we have $f(-3) = 2^{-3} = \left(\frac{1}{2}\right)^3 = \frac{1}{8}$. If we choose smaller and smaller $x$ values, the function values will be smaller and smaller fractions. For example, if $x = -10$, we have $f(-10) = 2^{-10} = \left(\frac{1}{2}\right)^{10} = \frac{1}{1024}$. Notice that none of the $x$ values we choose will result in a function value of 0. (This is the case because the numerator of the fraction will always be 1.) This tells us that while the domain of this function is the set of all real numbers, the range is limited to the set of positive real numbers. In the following example, you will examine the values of a similar function.

Example 1: For the function $g(x) = 3^x$, find $g(2)$, $g(4)$, $g(0)$, $g(-2)$, $g(-4)$.

Solution:

- $g(2) = 3^2 = 9$
- $g(4) = 3^4 = 81$
- $g(0) = 3^0 = 1$
- $g(-2) = 3^{-2} = \frac{1}{3^2} = \frac{1}{9}$
- $g(-4) = 3^{-4} = \frac{1}{3^4} = \frac{1}{81}$

The values of the function $g(x) = 3^x$ behave much like those of $f(x) = 2^x$: if we choose larger values of $x$, we get larger and larger function values. If $x = 0$, the function value is 1. And, if we choose smaller and smaller $x$ values, the function values will be smaller and smaller fractions. Also, the range of $g(x)$ is limited to positive values.

In general, if we have a function of the form $f(x) = a^x$, where $a$ is a positive real number, the domain of the function

205
is the set of all real numbers, and the range is limited to the set of positive real numbers. This restricted range will result in a specific shape of the graph.

**Graphing basic exponential functions**

Let's now consider the graph of \( f(x) = 2^x \). Above we found several function values, and we began to analyze the function in terms of large and small values of \( x \). The graph below shows this function, with several points marked in blue.

![Graph of \( f(x) = 2^x \)](image)

Notice that as \( x \) increases without bound, the function grows without bound. However, if \( x \) decreases without bound, the function values get closer and closer to 0. Therefore the function is asymptotic to the \( x \)-axis. This is the graphical result of the fact that the range of the function is limited to positive \( y \) values. Now let's consider the graph of \( g(x) = 3^x \) and \( h(x) = 4^x \).

**Example 2:** Use a graphing utility to graph \( f(x) = 2^x \), \( g(x) = 3^x \) and \( h(x) = 4^x \). How are the graphs the same, and how are they different?

**Solution:** \( f(x) = 2^x \), \( g(x) = 3^x \) and \( h(x) = 4^x \) are shown together below.
The graphs of the three functions have the same overall shape: they have the same end behavior, and they all contain the point (0, 1). The difference lies in their rate of growth. Notice that for positive \( x \) values, \( h(x) = 4^x \) grows the fastest and \( f(x) = 2^x \) grows the slowest. The function values for \( h(x) = 4^x \) are highest and the function values for \( f(x) = 2^x \) are the lowest for any given value of \( x \) when \( x \) is a positive value. For negative \( x \) values, the relationship changes: \( f(x) = 2^x \) has the highest function values of the three functions for any given value of \( x \).

Now that we have examined these three parent graphs, we will graph using shifts, reflections, stretches and compressions.

### Graphing exponential functions using transformations

Above we graphed the function \( f(x) = 2^x \). Now let’s consider a related function: \( g(x) = 2^x + 3 \). Every function value will be a power of 2, plus 3. The table below shows several values for the function:

\[
g(x) = 2^x + 3
\]

<table>
<thead>
<tr>
<th>( x )</th>
<th>( g(x) = y )</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-2)</td>
<td>(2^{-2} + 3 = \frac{1}{4} + 3 = 3\frac{1}{4})</td>
</tr>
<tr>
<td>(-1)</td>
<td>(2^{-1} + 3 = \frac{1}{2} + 3 = 3\frac{1}{2})</td>
</tr>
<tr>
<td>(0)</td>
<td>(2^0 + 3 = 1 + 3 = 4)</td>
</tr>
<tr>
<td>(1)</td>
<td>(2^1 + 3 = 2 + 3 = 5)</td>
</tr>
<tr>
<td>(2)</td>
<td>(2^2 + 3 = 4 + 3 = 7)</td>
</tr>
<tr>
<td>(3)</td>
<td>(2^3 + 3 = 8 + 3 = 11)</td>
</tr>
</tbody>
</table>

The function values follow the same kind of pattern as the values for \( f(x) = 2^x \). However, because every function value is 3 more than a power of 2, the horizontal asymptote of the function is the line \( y = 3 \). The graph of this
5.5. Exponential Functions

function and the horizontal asymptote are shown below.

From your study of transformation of functions in the chapter where you were asked to graph quadratic functions, you may notice that the graph of \( g(x) = 2^x + 3 \) can be viewed as a vertical shift of the graph of \( f(x) = 2^x \). In general, we can produce a graph of an exponential function with base 2 if we analyze the equation of the function in terms of transformations. The table below summarizes the different kinds of transformations of \( f(x) = 2^x \). The issue of stretching will be discussed further below the table.

**Table 5.2:**

<table>
<thead>
<tr>
<th>Equation</th>
<th>Relationship to ( f(x)=2^x )</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>( g(x) = 2^{x-a}, \text{ for } a &gt; 0 )</td>

<td>Obtain a graph of ( g ) by reflecting the graph of ( f ) over the ( y )-axis.</td>
<td>( y &gt; 0 )</td>
</tr>
</tbody>
</table>

As was discussed in prior chapters, a stretched graph could also be seen as a compressed graph. This is not the case for exponential functions because of the \( x \) in the exponent. Consider the function \( s(x) = 2(2^x) \) and \( c(x) = 2^{3x} \). The first function represents a vertical stretch of \( f(x) = 2^x \) by a factor of 2. The second function represents a horizontal compression of \( f(x) = 2^x \) by a factor of 3. The function \( c(x) \) is actually the same as another parent function: \( c(x) = 2^{3x} = (2^3)^x = 8^x \). The function \( s(x) \) is actually the same as a shift of \( f(x) = 2^x \): \( s(x) = 2(2^x) = 2^1 \cdot 2^x = 2^x + 1 \). The graphs
of \( s \) and \( c \) are shown below. Notice that the graph of \( c \) has a \( y \)-intercept of 1, while the graph of \( s \) has a \( y \)-intercept of 2:

![Graph of s and c](image)

**Example 3:** Use transformations to graph the functions (a) \( a(x) = 3^x + 2 \) and (b) \( b(x) = -3^x + 4 \)

**Solution:**

a. \( a(x) = 3^x + 2 \)

This graph represents a shift of \( y = 3^x \) two units to the left. The graph below shows this relationship between the graphs of these two functions:

![Graph of a(x)](image)

b. \( b(x) = -3^x + 4 \)

This graph represents a reflection over the \( y \)-axis and a vertical shift of 4 units. You can produce a graph of \( b(x) \)
using three steps: sketch \( y = 3^x \), reflect the graph over the \( x \)-axis, and then shift the graph up 4 units. The graph below shows this process:

While you can always quickly create a graph using a graphing utility, using transformations will allow you to sketch a graph relatively quickly on your own. If we start with a parent function such as \( y = 3^x \), you can quickly plot several points: (0, 1), (2, 9), (-1, 1/3), etc. Then you can transform the graph, as we did in the previous example.

Notice that when we sketch a graph, we choose \( x \) values, and then use the equation to find \( y \) values. But what if we wanted to find an \( x \) value, given a \( y \) value? This requires solving exponential equations.

**Solving exponential equations**

Solving an exponential equation means determining the value of \( x \) for a given function value. For example, if we have the equation \( 2^x = 8 \), the solution to the equation is the value of \( x \) that makes the equation a true statement. Here, the solution is \( x = 3 \), as \( 2^3 = 8 \).

Consider a slightly more complicated equation \( 3(2^x + 1) = 24 \). We can solve this equation by writing both sides of the equation as a power of 2:

\[
\begin{align*}
2^{x+1} &= 2^3 \\
2^{x+1} &= 8 \\
\frac{3(2^{x+1})}{3} &= \frac{24}{3} \\
3(2^{x+1}) &= 24
\end{align*}
\]

To solve the equation now, recall a property of exponents: if \( b^x = b^y \), then \( x = y \). That is, if two powers of the same base are equal, the exponents must be equal. This property tells us how to solve:

\[
\begin{align*}
x &= 2 \\
\Rightarrow x + 1 &= 3 \\
2^{x+1} &= 2^3
\end{align*}
\]

Checking the solution, we see that:
Example 4: Solve the equation $5^{6x+10} = 25^{x-1}$

Solution: Use the same technique as shown above:

$x = -3$
$4x = -12$
$4x + 10 = -2$

$\Rightarrow 6x + 10 = 2x - 2$
$5^{6x} + 10 = 5^{2x} - 2$
$5^{6x} + 10 = (5^2)^x - 1$
$5^{6x} + 10 = 25^x - 1$

Checkin the solution we see that:

$5^{6(-3)+10} = 25^{-3-1}$
$5^{-18+10} = 25^{-4}$
$5^{-8} = 25^{-4}$

$\frac{1}{5^8} = \frac{1}{25^4}$
$\frac{1}{390625} = \frac{1}{390625}$

In both of the examples of solving equations, it was possible to solve because we could write both sides of the equations as a power of the same exponent. But what if that is not possible?

Consider for example the equation $3^x = 12$. If you try to figure out the value of $x$ by considering powers of 3, you will quickly discover that the solution is not a whole number. Later in the chapter we will study techniques for solving more complicated exponential equations. Here we will solve such equations using graphs.

Consider the function $y = 3^x$. We can find the solution to the equation $3^x = 12$ by finding the intersection of $y = 3^x$ and the horizontal line $y = 12$. Using a graphing calculator’s intersection capability, you should find that the approximate solution is $x \approx 2.26$.  

$3(2^{2+1}) = 3(2^3) = 3(8) = 24$
Example 5: Use a graphing utility to solve each equation:

<table>
<thead>
<tr>
<th>Table 5.3:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. (2^{3x-1} = 7)</td>
</tr>
</tbody>
</table>

Solution:

a. \(2^{3x-1} = 7\)

Graph the function \(y = 2^{3x-1}\) and find the point where the graph intersects the horizontal line \(y = 7\). The solution is \(x \approx 1.27\).
b. $6^{-4x} = 2^{8x-5}$

Graph the functions $y = 6^{-4x}$ and $y = 2^{8x-5}$ and find their intersection point.

The solution is $x \approx 0.27$. (Your graphing calculator should show 9 digits: 0.272630365.)

In the examples we have considered so far, the bases of the functions have been positive integers. Now we will examine a sub-family of exponential functions with a special base: the number $e$.

**The number $e$ and the function $y = e^x$**

In your previous studies of math, you have likely encountered the number $\pi$. The number $e$ is much like $\pi$. First, both are *irrational* numbers: they cannot be expressed as fractions. Second, both numbers are *transcendental*: they are not the solution of any polynomial with rational coefficients.

Like $\pi$, mathematicians found $e$ to be a natural constant in the world. One way to discover $e$ is to consider the function $f(x) = (1 + \frac{1}{x})^x$. The graph of this function is shown below.
Notice that as \( x \) increases without bound, the graph of the function gets closer to a horizontal asymptote around \( y \approx 2.7 \). If you examine several function values for \( f(x) \), you will see that this number is not exactly 2.7. In the table below, let \( y = f(x) \).

### Table 5.4:

<table>
<thead>
<tr>
<th>( x )</th>
<th>( y )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(not defined)</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>2.25</td>
</tr>
<tr>
<td>5</td>
<td>2.48832</td>
</tr>
<tr>
<td>10</td>
<td>2.5937424601</td>
</tr>
<tr>
<td>50</td>
<td>2.69158802907</td>
</tr>
<tr>
<td>100</td>
<td>2.70481382942</td>
</tr>
<tr>
<td>1000</td>
<td>2.71692393224</td>
</tr>
<tr>
<td>5000</td>
<td>2.7180100501</td>
</tr>
<tr>
<td>10,000</td>
<td>2.71814592683</td>
</tr>
<tr>
<td>50,000</td>
<td>2.7181825464614</td>
</tr>
</tbody>
</table>

Around \( x = 100 \), the function values pass 2.7, but they will never reach 2.8. As \( x \) increase without bound, the output values of the function get closer and closer to the constant \( e \). The value of \( e \) is approximately 2.7182818285. Again, like \( \pi \), we have to approximate the value of \( e \) because it is irrational.

The number \( e \) is used as the base of functions that can be used to model situations that involve growth or decay. For example, as you will learn later in the chapter, one method of calculating interest on a bank account or investment uses this number. Here we will examine the function \( y = e^x \) in order to verify that its graph is similar to the other exponential functions we have graphed.

The graph below shows \( y = e^x \), along with \( y = 2^x \) and \( y = 3^x \).
The graph of \( y = e^x \) (in green) has the same shape as the graphs of the other exponential functions. It sits in between the graphs of the other two functions, and notice that the graph is closer to \( y = 3^x \) than to \( y = 2^x \). This is reasonable because the value of \( e \) is closer to 3 than it is to 2. All three graphs have the same \( y \)-intercept: \((0, 1)\). Thus the graph of this function is clearly a member of the same family, even though the base of the function is an irrational number.

**Lesson Summary**

This lesson has introduced the family of exponential functions. We have examined values of functions, towards understanding the behavior of graphs. In general, exponential functions have a horizontal asymptote, though one end of the function increases (or decreases, if it is a reflection) without bound.

In this lesson we have graphed these functions, solved certain exponential equations using our knowledge of exponents, and solved more complicated equations using graphing utilities. We have also examined the function \( y = e^x \), which is a special member of the exponential family. In the coming lessons you will continue to learn about exponential functions, including the inverses of these functions, applications of these functions, and solving more complicated exponential equations using algebraic techniques.

**Points to Think About**

1. Why do exponential functions have horizontal asymptotes and not vertical asymptotes?
2. What would the graph of the inverse of an exponential function look like? What would its domain and range be?
3. How could you solve or approximate a solution to an exponential equation without using a graphing calculator?

**Vocabulary**

**\( e \)**

The number \( e \) is a transcendental number, often referred to as Euler’s constant. Several mathematicians are credited with early work on \( e \). Euler was the first to use this letter to represent the constant. The value of \( e \) is approximately 2.71828.

**Exponential Function**

An exponential function is a function for which the input variable \( x \) is in the exponent of some base \( b \), where \( b \) is a real number.
Irrational number
An irrational number is a number that cannot be expressed as a fraction of two integers.

Transcendental number
A transcendental number is a number that is not a solution to any non-zero polynomial with rational roots.

The number is a transcendental number. It is the ratio of the circumference to the diameter in any circle.
5.6 Finding Equations of Exponential Functions

Here you’ll learn how to determine whether certain models fit data.

An exponential function is a function of the form \( y = ab^x \), where \( a \neq 0, b > 0 \), and \( b \neq 1 \). To find an equation of an exponential function is to find \( a \) and \( b \) in \( y = ab^x \).

**Example 1:**

Find an equation of the form \( y = ab^x \) of the exponential curve that passes through the points (0, 5) and (1, 15). The points (0, 5) and (1, 15) are on the curve so they satisfy the equation \( y = ab^x \). We first plug in the point (0, 5).

\[
5 = ab^0 \quad \text{Substitute 0 for } x \text{ and 5 for } y \text{ then solve for } a
\]

\[
5 = a
\]

Our equation is now \( y = 5b^x \). We then use the second point (1, 15).

\[
15 = 5b^1 \quad \text{Substitute 1 for } x \text{ and 15 for } y \text{ then solve for } b
\]

\[
3 = b
\]

\[
y = 5(3)^x \quad \text{Write the equation}
\]

**Example 2:**

Find an equation of the form \( y = ab^x \) of the exponential curve that passes through the points (0, 8) and (4, 79).

\[
8 = ab^0 \quad \text{Substitute 0 for } x \text{ and 8 for } y \text{ then solve for } a
\]

\[
8 = a
\]

\[
y = 8b^x
\]

\[
79 = 8b^4 \quad \text{Substitute 4 for } x \text{ and 79 for } y \text{ then solve for } b
\]

\[
\frac{79}{8} = b^4
\]

\[
\pm (\frac{79}{8})^{1/4} = b \quad \text{We use the positive root since we must have}
\]

\[
(\frac{79}{8})^{1/4} = b
\]

\[
1.77 \approx b
\]

\[
y = 8(1.77)^x
\]

In each of the previous examples, the y-intercept (0, \( a \)) was given. In the following example, we will approach the problem differently since the y-intercept is not provided.

**Example 3:**

Find an equation of the form \( y = ab^x \) of the exponential curve that passes through the points (2, 5) and (3, 10).

\[
10 = ab^3 \quad \text{Substitute 3 for } x \text{ and 10 for } y
\]

\[
5 = ab^2 \quad \text{Substitute 2 for } x \text{ and 5 for } y
\]

\[
\frac{10}{5} = \frac{ab^3}{ab^2} \quad \text{Divide}
\]

\[
2 = b \quad \text{Solve for } b
\]
5.6. Finding Equations of Exponential Functions

\[ y = a(2)^x \]

\[ 5 = a(2)^2 \quad \text{Substitute 2 for } x \text{ and } 5 \text{ for } y \]

\[ 5 = 4a \]

\[ 1.25 = a \]

\[ y = 1.25(2)^x \]

**Example 4:**

You are told that the population of a certain type of bacteria is growing exponentially. To verify this, you conduct your own experiment. Initially at time \( t = 0 \) minute you counted and observed that there are 3 bacteria in a tube. Two minutes later the number of bacteria is 48. Find an exponential equation to predict the number of bacteria at any time \( t \). Use this equation to predict the bacteria population in the tube ten minutes later.

After reading the question carefully, our task is to first find an exponential equation. The points \((0, 3)\) and \((2, 48)\) must satisfy the equation \( y = ab^x \) we are looking for:

\[ 3 = ab^0 \quad \text{Substitute 0 for } x \text{ and } 3 \text{ for } y \]

\[ 3 = a \]

\[ y = 3b^x \]

\[ 48 = 3(b)^2 \quad \text{Substitute 2 for } x \text{ and } 48 \text{ for } y \]

\[ 16 = b^2 \quad \text{Solve for } b^2 \]

\[ \pm 4 = b \quad \text{Solve for } b \]

But since \( b > 0 \) we pick \( b = 4 \). Thus the equation is \( y = 3(4)^x \). To find the number of bacteria in the tube after 10 minutes: \( y = 3(4)^{10} = 3145728 \), which is well above 3 million bacteria.

*Now suppose you recorded the high temperature for each day of the year. If you wanted to model this data with a function, how would you decide whether to use a linear model or exponential model. Could your graphing calculator help you decide? If so, what buttons would you have to push on your calculator in order to get relevant information? In this Concept, you’ll learn about using linear and exponential models for data sets such as the one described.*

**Guidance**

So far you have learned how to graph two very important types of equations.

- Linear equations in slope-intercept form: \( y = mx + b \)
- Exponential equations of the form: \( y = a(b)^x \)

In real-world applications, the function that describes some physical situation is not given. Finding the function is an important part of solving problems. For example, scientific data such as observations of planetary motion are often collected as a set of measurements given in a table. One job for a scientist is to figure out which function best fits the data. In this Concept, you will learn some methods that are used to identify which function describes the relationship between the dependent and independent variables in a problem.

**Using Differences to Determine the Model**

By finding the differences between the dependent values (output), we can determine if the model is linear, exponential, or neither.

- If the difference is the same value, the model will be **linear**
• If the difference is the same ratio, the model will be exponential

Example A

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
<th>difference of y-values</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>-4</td>
<td>-1 + 4 = 3</td>
</tr>
<tr>
<td>-1</td>
<td>-1</td>
<td>2 + 1 = 3</td>
</tr>
<tr>
<td>0</td>
<td>2</td>
<td>5 - 2 = 3</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>8 - 5 = 3</td>
</tr>
<tr>
<td>2</td>
<td>8</td>
<td></td>
</tr>
</tbody>
</table>

The first difference is the same value (3). This data can be modeled using a linear regression line.

The equation to represent this data is \( y = 3x + 2 \).

When we look at the difference of the y-values, we must make sure that we examine entries for which the x-values increase by the same amount.

Using Ratios to Determine the Model

By taking the ratio of the values, one can determine whether the model is exponential.

If the ratio of dependent values is the same, then the data is modeled by an exponential equation, as in the example below.
5.6. Finding Equations of Exponential Functions

Example B

The equation to represent this data is \( y = 4(3)^x \)

Guided Practice

Determine whether the function in the given table is linear or exponential.

<table>
<thead>
<tr>
<th>( x )</th>
<th>( y )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>5</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>3</td>
<td>20</td>
</tr>
<tr>
<td>4</td>
<td>25</td>
</tr>
<tr>
<td>6</td>
<td>35</td>
</tr>
</tbody>
</table>

Solution:

At first glance, this function might not look linear because the difference in the \( y \)-values is not always the same.
However, we see that the difference in y-values is 5 when we increase the x-values by 1, and it is 10 when we increase the x-values by 2. This means that the difference in y-values is always 5 when we increase the x-values by 1. Therefore, the function is linear.

The equation is modeled by $y=5x+5$. 
5.7. Composite Functions and Inverse Functions

Learning objectives

- Evaluate and find composite functions.
- Find the inverse of a function
- Determine if a function is invertible
- State the domain and range for a function and its inverse
- Graph functions and their inverses
- Use composition to verify if two functions are inverses.

Introduction

In this chapter, we will focus on two related functions: exponential functions, and logarithmic functions. These two functions have a special relationship with one another: they are inverses of each other. In this first lesson, we will develop the idea of inverses, both algebraically and graphically, as background for studying these two types of functions in depth. We will begin with a familiar, every-day example of two functions that are inverses.

Composite Functions

A composite function or composition of functions is a function made up of more than one function. A composite function can be thought of as a function inside another function. The notation used for composition of functions is:

\[ (f \circ g)(x) = f(g(x)) \]

To calculate a composite function, we evaluate the inner function and then substitute the result into the outer function. We can say the output of the inner function, \( g(x) \), becomes the input into the outer function.

Sometimes we find composite function values if the initial input is a given value or real number. In this case, the composite function value is a real number. However, if the initial input is a variable or variable expression, the composite function is another function. Let’s look at examples of both cases.

**Example 1:** Find the composite function values \((f \circ g)(3)\) and \((g \circ f)(3)\), given \(f(x) = x^2 - 2x + 1\) and \(g(x) = x - 5\).

a) \((f \circ g)(3) = f(g(3))\)

We start by determining the inner function value, \(g(3)\).

\[ g(3) = 3 - 5 = -2 \]

Now substitute \(-2\) for \(g(3)\) in the composite function since \(g(3) = 2\).

\[ f(g(3)) = f(-2) \]

Now we find the function value \(f(-2)\).
\[ f(-2) = (-2)^2 - 2(-2) + 1 = 4 + 4 + 1 = 9 \]

Therefore, \( f(g(3)) = 9 \)

b) \( (g \circ f)(3) = g(f(3)) \)

We start by determining the inner function value, \( f(3) \).

\[ f(3) = (3)^2 - 2(3) + 1 = 9 - 6 + 1 = 4 \]

Now substitute 4 for \( f(3) \) in the composite function since \( f(3) = 4 \).

\[ g(f(3)) = g(4) \]

Now we find the function value \( g(4) \).

\[ g(4) = 4 - 5 = -1 \]

Therefore, \( g(f(3)) = -1 \)

Notice the result is a real number value.

Now we will look at a composition of functions that results in another function.

**Example 2:** Find the composite functions \( (f \circ g)(x) \) and \( (g \circ f)(x) \), given \( f(x) = x^2 - 2x + 1 \) and \( g(x) = x - 5 \).

a) \( (f \circ g)(x) = f(g(x)) \)

Notice we can not evaluate \( g(x) \) because we are not given an input for \( g(x) \). As a result, the input into \( f(x) \) is \( g(x) \).

\[ f(g(x)) = f(x - 5) = (x - 5)^2 - 2(x - 5) + 1 = x^2 - 10x + 25 - 2x + 10 + 1 = x^2 - 12x + 36 \]

\[ f(g(x)) = x^2 - 12x + 36 \]

Notice the composite function is another function.

b) \( (g \circ f)(x) = g(f(x)) \)

Notice we can not evaluate \( f(x) \) because we are not given an input for \( f(x) \). As a result, the input into \( g(x) \) is \( f(x) \).

\[ g(f(x)) = g(x^2 - 2x + 1) = (x^2 - 2x + 1) - 5 = x^2 - 2x - 4 \]

\[ g(f(x)) = x^2 - 2x - 4 \]

Notice the composite function is another function.
Functions and inverses

In the United States, we measure temperature using the Fahrenheit scale. In other countries, people use the Celsius scale. The equation \( C = \frac{5}{9}(F - 32) \) can be used to find \( C \), the Celsius temperature, given \( F \), the Fahrenheit temperature. If we write this equation using function notation, we have \( t(x) = \frac{5}{9}(x - 32) \). The input of the function is a Fahrenheit temperature, and the output is a Celsius temperature. For example, the freezing point on the Fahrenheit scale is 32 degrees. We can find the corresponding Celsius temperature using the function:

\[
t(32) = \frac{5}{9}(32 - 32) = \frac{5}{9} \cdot 0 = 0
\]

This function allows us to convert a Fahrenheit temperature into Celsius, but what if we want to convert from Celsius to Fahrenheit?

Consider again the equation above: \( C = \frac{5}{9}(F - 32) \). We can solve this equation to isolate \( F \):

\[
\begin{align*}
C &= \frac{5}{9}(F - 32) \\
\frac{9}{5}C &= \frac{9}{5} \cdot \frac{5}{9}(F - 32) \\
\frac{9}{5}C &= F - 32 \\
\frac{9}{5}C + 32 &= F
\end{align*}
\]

If we write this equation using function notation, we get \( f(x) = \frac{9}{5}x + 32 \). For this function, the input is the Celsius temperature, and the output is the Fahrenheit temperature. For example, if \( x = 0 \), \( f(0) = \frac{9}{5}(0) + 32 = 0 + 32 = 32 \).

Now consider the functions \( t(x) = \frac{5}{9}(x - 32) \) and \( f(x) = \frac{9}{5}x + 32 \) together. The input of one function is the output of the other. This is an informal way of saying that these functions are inverses. Formally, the inverse of a function is defined as follows:

**Inverse Function**

Functions \( f(x) \) and \( g(x) \) are inverses if

\[
f(g(x)) = x \quad \text{and} \quad g(f(x)) = x \quad \text{which can also be written} \quad f \circ g = x \quad \text{and} \quad g \circ f = x.
\]

The following notation is used to indicate inverse functions:

If \( f(x) \) and \( g(x) \) are inverses, then

\[
f(x) = g^{-1}(x) \quad \text{and} \quad g(x) = f^{-1}(x)
\]

with can also be written \( f = g^{-1} \) and \( g = f^{-1} \).

Note: \( f^{-1}(x) \) does not equal \( \frac{1}{f(x)} \).

Informally, we define the inverse of a function as the relation we obtain by switching the domain and range of the function. Because of this definition, you can find an inverse by switching the roles of \( x \) and \( y \) in an equation. For example, consider the function \( g(x) = 2x \). This is the line \( y = 2x \). If we switch \( x \) and \( y \), we get the equation \( x = 2y \). Dividing both sides by 2, we get \( y = \frac{1}{2}x \). Therefore the functions \( g(x) = 2x \) and \( y = \frac{1}{2}x \) are inverses. Using function notation, we can write \( y = \frac{1}{2}x \) as \( g^{-1}(x) = \frac{1}{2}x \).

**Example 3:** Find the inverse of each function.

a. \( f(x) = 5x - 8 \)
b. \( f(x) = x^3 \)

a. First write the function using \( y = \) notation, then interchange \( x \) and \( y \):
Solution:

\[ f(x) = 5x - 8 \implies y = 5x - 8 \]

Interchanging \( x \) and \( y \): \( x = 5y - 8 \)

Then isolate \( y \):

\[
\begin{align*}
  x &= 5y - 8 \quad (\text{Add 8 to both sides.}) \\
  x + 8 &= 5y \quad (\text{Divide both sides by 5.}) \\
  y &= \frac{1}{5}x + \frac{8}{5}
\end{align*}
\]

So the inverse is:

\[ f^{-1}(x) = \frac{1}{5}x + \frac{8}{5} \] (Written using inverse function notation)

b. First write the function using \( y = \) notation, the interchange \( x \) and \( y \).

\[ f(x) = x^3 \implies y = x^3 \]

Interchanging \( x \) and \( y \): \( x = y^3 \)

Then isolate \( y \):

\[
\begin{align*}
  y &= \sqrt[3]{x} \quad (\text{Cube root both sides.}) \\
  y &= \sqrt[3]{x}
\end{align*}
\]

So the inverse is:

\[ f^{-1}(x) = \sqrt[3]{x} \] (Written using inverse function notation)

Because of the definition of inverse, the graphs of inverses are reflections across the line \( y = x \). Recall in an earlier example we found a function \( t(x) \) that converted degrees Fahrenheit to degree Celsius, and another function \( f(x) \) that converted degrees Celsius to degrees Fahrenheit. They were inverses of each other. The graph below shows \( t(x) = \frac{5}{9}(x - 32) \) and \( f(x) = \frac{9}{5}x + 32 \) on the same graph, along with the reflection line \( y = x \).

A note about graphing with software or a graphing calculator: if you look at the graph above, you can see that the lines are reflections over the line \( y = x \). However, if you do not view the graph in a window that shows equal scales of the \( x \)- and \( y \)-axes, the graph might not look like this.
Before continuing, there are two other important things to note about inverses. First, remember that the ‘-1’ is not an exponent, but a symbol that represents an inverse. Second, not every function has an inverse that is a function. In the examples we have considered so far, we inverted a function, and the resulting relation was also a function. However, some functions are not invertible; that is, following the process of "inverting" them does not produce a relation that is a function. We will return to this issue below when we examine domain and range of functions and their inverses. First we will look at a set of functions that are invertible.

**Inverses of 1-to-1 functions**

Consider again example 1. We began with the function $f(x) = x^3$, and we found the inverse $f^{-1}(x) = \sqrt[3]{x}$. The graphs of these functions are show below.
The function $f(x) = x^3$ is an example of a **one-to-one function**, which is defined as follows:

**Table 5.6:**

**One to one**

A function is **one-to-one** if and only if every element of its domain corresponds to *exactly* one element of its range.

The linear functions we examined above are also one-to-one. The function $y = x^2$, however, is not one-to-one. The graph of this function is shown below.

You may recall that you can identify a relation as a function if you draw a vertical line through the graph, and the line touches only one point. Notice then that if we draw a horizontal line through $y = x^2$, the line touches more than
one point. Therefore if we inverted the function, the resulting graph would be a reflection over the line \( y = x \), and the inverse would not be a function. It fails the vertical line test.

You may recall that you can identify a relation as a function if you draw a vertical line through the graph, and the line touches only one point. Notice then that if we draw a horizontal line through \( y = x^2 \), the line touches more than one point. Therefore if we inverted the function, the resulting graph would be a reflection over the line \( y = x \), and the inverse would not be a function. It fails the vertical line test.

The function \( y = x^2 \) is therefore not a one-to-one function. A function that is one-to-one will be invertible. You can determine this graphically by drawing a horizontal line through the graph of the function. For example, if you draw a horizontal line through the graph of \( f(x) = x^3 \), the line will only touch one point on the graph, no matter where you draw the line.

**Example 4:** Graph the function \( f(x) = \frac{1}{3}x + 2 \). Use a horizontal line test to verify that the function is invertible.

**Solution:** The graph below shows that this function is invertible. We can draw a horizontal line at any \( y \) value, and the line will only cross \( f(x) = \frac{1}{3}x + 2 \) once.

In summary, a one-to-one function is invertible. That is, if we invert a one-to-one function, its inverse is also a function. Now that we have established what it means for a function to be invertible, we will focus on the domain and range of inverse functions.

**Domain and range of functions and their inverses**

Because of the definition of inverse, a function’s domain is its inverse’s range, and the inverse’s domain is the functions range. This statement may seem confusing without a specific example.

**Example 3:** State the domain and range of the function and its inverse:

Function: \( \{(1, 2), (2, 5), (3, 7)\} \)

**Solution:** The inverse of this function is the set of points \( \{(2, 1), (5, 2), (7, 3)\} \)

The domain of the function is \( \{1, 2, 3\} \). This is also the range of the inverse.
The range of the function is \( \{2, 5, 7\} \). This is also the domain of the inverse.

The linear functions we examined previously, as well as \( f(x) = x^3 \), all had domain and range both equal to the set of all real numbers. Therefore the inverses also had domain and range equal to the set of all real numbers. Because the domain and range were the same for these functions, switching them maintained that relationship.

Also, as we found above, the function \( y = x^2 \) is not one-to-one, and hence it is not invertible. That is, if we invert it, the resulting relation is not a function. We can change this situation if we define the domain of the function in a more limited way. Let \( f(x) \) be a function defined as follows: \( f(x) = x^2 \), with domain limited to all real numbers greater than or equal to 0. Then the inverse of the function is the square root function: \( f^{-1}(x) = \sqrt{x} \)

**Example 5:** Define the domain for the function \( f(x) = (x - 2)^2 \) so that \( f \) is invertible.

**Solution:** The graph of this function is a parabola. We need to limit the domain to one side of the parabola. Conventionally in cases like these we choose the positive side; therefore, the domain is limited to all real numbers greater than or equal to 2.

**Inverse functions and composition**

In the examples we have considered so far, we have taken a function and found its inverse. We can also analyze two functions and determine whether or not they are inverses. Recall the formal definition from earlier.

Two functions \( f(x) \) and \( g(x) \) are inverses if and only if \( f(g(x)) = x \) and \( g(f(x)) = x \).

This definition is perhaps easier to understand if we look at a specific example. Let's use two functions that we have established as inverses: \( f(x) = 2x \) and \( g(x) = \frac{1}{2}x \). Let's also consider a specific \( x \) value. Let \( x = 8 \). Then we have \( f(g(8)) = f(\frac{1}{2}(8)) = f(4) = 2(4) = 8 \). Similarly, we could establish that \( g(f(8)) = 8 \). Notice that there is nothing special about \( x = 8 \). For any \( x \) value we input into \( f \), the same value will be output by the composed functions:

\[
\begin{align*}
  f(g(x)) &= f(\frac{1}{2}x) = 2(\frac{1}{2}x) = x \\
  g(f(x)) &= g(2x) = \frac{1}{2}(2x) = x
\end{align*}
\]

**Example 6:** Use composition of functions to determine if \( f(x) = 2x + 3 \) and \( g(x) = 3x - 2 \) are inverses.

**Solution:** The functions are not inverses.

We only need to check one of the compositions:

\[
  f(g(x)) = f(3x - 2) = 2(3x - 2) + 3 = 6x - 4 + 3 = 6x - 1 \neq x
\]

**Lesson Summary**

In this lesson we have defined the concept of inverse, and we have examined functions and their inverses, both algebraically and graphically. We established that functions that are one-to-one are invertible, while other functions are not necessarily invertible. (However, we can redefine the domain of a function such that it is invertible.) In the remainder of the chapter we will examine two families of functions whose members are inverses.
Points To Think About

1. Can a function be its own inverse? If so, how?
2. Consider the other function families you learned about in previous chapters. What do their inverses look like?
3. How is the rate of change of a linear function related to the rate of change of the functions inverse?

Vocabulary

**Inverse**
The inverse of a function is the relation obtained by interchanging the domain and range of a function.

**Invertible**
A function is invertible if its inverse is a function.

**One-to-one**
A function is one-to-one if every element of its domain is paired with exactly one element of its range.
Logarithmic Functions

Chapter Outline

6.1  LOGARITHMIC FUNCTIONS
6.2  PROPERTIES OF LOGARITHMS
6.3  EXPONENTIAL AND LOGARITHMIC MODELS AND EQUATIONS
6.4  COMPOUND INTEREST
6.5  GROWTH AND DECAY
6.6  LOGARITHMIC SCALES.
6.1 Logarithmic Functions

Learning objectives

• Translate numerical and algebraic expressions between exponential and logarithmic form.
• Evaluate logarithmic functions.
• Determine the domain of logarithmic functions.
• Graph logarithmic functions.
• Solve logarithmic equations.

Introduction

In the previous lesson we examined exponential expressions and functions. Now we will consider another representation for the same relationships involved in exponential expressions and functions.

Consider the function \( y = 2^x \). Every \( x \)-value of this function is an exponent. Every \( y \)-value is a power of 2. As you learned in an earlier lesson, functions that are one-to-one have inverses that are functions. This is the case with exponential functions. If we take the inverse of \( y = 2^x \) (by interchanging the domain and range) we obtain this equation: \( x = 2^y \). In order to write this equation such that \( y \) is expressed as a function of \( x \), we need a different notation.

The solution to this problem is found in the logarithm. John Napier originally introduced the logarithm to 17th century mathematicians as a technique for simplifying complicated calculations. While today’s technology allows us to do most any calculations we could imagine, logarithmic functions continue to be a focus of study in mathematics, as a useful way to work with exponential expressions and functions.

Changing Between Exponential and Logarithmic Expressions

Every exponential expression can be written in logarithmic form. For example, the equation \( x = 2^y \) is written as follows: \( y = \log_2 x \). In general, the equation \( \log_b n = a \) is equivalent to the equation \( b^a = n \). That is, \( b \) is the base, \( a \) is the exponent, and \( n \) is the power, or the number you obtain by raising \( b \) to the power of \( a \). Sometimes \( n \) is also referred to as the argument of the logarithm. Notice that the exponential form of an expression emphasizes the power, while the logarithmic form emphasizes the exponent. More simply put, a logarithm (or log for short) is an exponent.
We can write any exponential expression in logarithmic form.

**Example 1:** Rewrite each exponential expression as a log expression.

<table>
<thead>
<tr>
<th>TABLE 6.1:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a. $3^4 = 81$</td>
<td>b. $b^{4x} = 52$</td>
</tr>
</tbody>
</table>

**Solution:**

a. In order to rewrite an expression, you must identify its base, its exponent, and its power. The 3 is the base, so it is placed as the subscript in the log expression. The 81 is the power, and so it is placed after the log. Thus we have: $3^4 = 81$ is the same as $\log_3 81 = 4$.

b. The $b$ is the base, and the expression $4x$ is the exponent, so we have: $\log_b 52 = 4x$. We say, log base $b$ of 52, equals $4x$.

To read this expression, we say the logarithm base 3 of 81 equals 4. This is equivalent to saying 3 to the $4^{th}$ power equals 81.

We can also express a logarithmic statement in exponential form.

**Example 2:** Rewrite the logarithmic expressions in exponential form.

<table>
<thead>
<tr>
<th>TABLE 6.2:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a. $\log_{10} 100 = 2$</td>
<td>b. $\log_b w = 5$</td>
</tr>
</tbody>
</table>

**Solution:**

a. The base is 10, and the exponent is 2, so we have: $10^2 = 100$

b. The base is $b$, and the exponent is 5, so we have: $b^5 = w$.

Perhaps the most common example of a use of a logarithm is the Richter scale, which measures the magnitude of an earthquake. The magnitude is actually the logarithm base 10 of the amplitude of the quake. That is, $m = \log_{10} A$. This means that, for example, an earthquake of magnitude 4 is 10 times as strong as an earthquake with magnitude 3. We can see why this is true of we look at the logarithmic and exponential forms of the expressions: An earthquake of magnitude 3 means $3 = \log_{10} A$. The exponential form of this expression is $10^3 = A$. Thus the amplitude of the quake is 1,000. Similarly, a quake with magnitude 4 has amplitude $10^4 = 10,000$. We will return to this example in a future lesson.

**Evaluating Logarithmic Functions**

As noted above, a logarithmic function is the inverse of an exponential function. Consider again the function $y = 2^x$ and its inverse $x = 2^y$. Above, we rewrote the inverse $x = 2^y$ as $y = \log_2 x$. If we want to emphasize the fact that the log equation represents a function, we can write the equation as $f(x) = \log_2 x$. To evaluate this function, we choose values of $x$ and then determine the corresponding $y$ values, or function values.

**Example 3:** Evaluate the function $f(x) = \log_2 x$ for the values:
6.1. Logarithmic Functions

**Table 6.3:**

<table>
<thead>
<tr>
<th>a. x = 2</th>
<th>b. x = 1</th>
<th>c. x = -2</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Solution:

a. If \( x = 2 \), we have:

**Table 6.4:**

\[
\begin{align*}
  f(x) &= \log_2 x \\
  f(2) &= \log_2 2
\end{align*}
\]

To determine the value of \( \log_2 2 \), you can ask yourself: 2 to what power equals 2? Answering this question is often easy if you consider the exponential form: \( 2^?=2 \). The missing exponent is 1. So \( f(2) = \log_2 2 = 1 \).

b. If \( x = 1 \), we have:

**Table 6.5:**

\[
\begin{align*}
  f(x) &= \log_2 x \\
  f(1) &= \log_2 1
\end{align*}
\]

As we did in (a), we can consider exponential form: \( 2^?=1 \). The missing exponent is 0. So we have \( f(1) = \log_2 1 = 0 \).

c. If \( x = -2 \), we have:

**Table 6.6:**

\[
\begin{align*}
  f(x) &= \log_2 x \\
  f(-2) &= \log_2 -2
\end{align*}
\]

Again, consider the exponential form: \( 2^?=2 \). There is no such exponent. Therefore in the set of real numbers, \( f(-2) = \log_2 -2 \) does not exist as a real valued function.

Example 3c illustrates an important point: there are restrictions on the domain of a logarithmic function. For the function \( f(x) = \log_2 x \), \( x \) cannot be a negative number. Therefore we can state the domain of this function as: the set of all real numbers greater than 0. Formally, we can write it as a set: \( \{ x \in \mathbb{R} | x > 0 \} \). In general, the domain of a logarithmic function is restricted to those values that will make the argument of the logarithm non-negative.

For example, consider the function \( f(x) = \log_3(x-4) \). If you attempt to evaluate the function for \( x \) values of 4 or less, you will find that the function values do not exist. Therefore the domain of the function is \( \{ x \in \mathbb{R} | x > 4 \} \). The domain of a logarithmic function is one of several key issues to consider when graphing.

**Graphing Logarithmic Functions**

Because the function \( f(x) = \log_3 x \) is the inverse of the function \( g(x) = 2^x \), the graphs of these functions are reflections over the line \( y = x \). The figure below shows the graphs of these two functions:
We can see that the functions are inverses by looking at the graph. For example, the graph of \( g(x)=2^x \) contains the point (1, 2), while the graph of \( f(x)=\log_2 x \) contains the point (2, 1).

Also, note that while the graph of \( g(x)=2^x \) is asymptotic to the \( x \)-axis, the graph of \( f(x)=\log_2 x \) is asymptotic to the \( y \)-axis. This behavior of the graphs gives us a visual interpretation of the restricted range of \( g \) and the restricted domain of \( f \).

When graphing log functions, it is important to consider \( x \)-values across the domain of the function. In particular, we should look at the behavior of the graph as it gets closer and closer to the asymptote. Consider \( f(x)=\log_2 x \) for values of \( x \) between 0 and 1.

If \( x=1/8 \), then \( f(1/8)=\log_2(1/8)=-3 \) because \( 2^{-3}=1/8 \).
If \( x=1/4 \), then \( f(1/4)=\log_2(1/4)=-2 \) because \( 2^{-2}=1/4 \).
If \( x=1/2 \), then \( f(1/2)=\log_2(1/2)=-1 \) because \( 2^{-1}=1/2 \).

From these values you can see that if we choose \( x \) values that are closer and closer to 0, the \( y \) values decrease without bound. In terms of the graph, these values show us that the graph gets closer and closer to the \( y \)-axis. Formally we say that the vertical asymptote of the graph is \( x=0 \).

**Example 4:** Graph the function \( f(x)=\log_4 x \) and state the domain and range of the function.

**Solution:** The function \( f(x)=\log_4 x \) is the inverse of the function \( g(x)=4^x \). We can sketch a graph of \( f(x) \) by evaluating the function for several values of \( x \), or by reflecting the graph of \( g \) over the line \( y=x \).

If we choose to plot points, it is helpful to organize the points in a table: Let \( y = f(x) = \log_4(x) \)

<table>
<thead>
<tr>
<th>( x )</th>
<th>( y )</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/4</td>
<td>-1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>16</td>
<td>2</td>
</tr>
</tbody>
</table>
The graph is asymptotic to the y-axis, so the domain of f is the set of all real numbers that are greater than 0. We can write this as a set: \( \{ x \in \mathbb{R} | x > 0 \} \). While the graph might look as if it has a horizontal asymptote, it does in fact continue to rise. The range is the set of all real numbers.

A note about graphing calculators: You can use a graphing calculator to graph logarithmic functions, but many calculators will only allow you to use base 10 or base e. However, after the next lesson you will be able to rewrite any logarithm as a log with base 10 or base e.

In this section we have looked at graphs of logarithmic functions of the form \( f(x) = \log_b x \). Now we will consider the graphs of other forms of logarithmic equations.

**Graphing Logarithmic Functions Using Transformations**

As you saw in the previous lesson, you can graph exponential functions by considering the relationships between equations. For example, you can use the graph of \( f(x) = 2^x \) to sketch a graph of \( g(x) = 2^x + 3 \). Every y value of \( g(x) \) is the same as a y value of \( f(x) \), plus 3. Therefore we can shift the graph of \( f(x) \) up 3 units to obtain a graph of \( g(x) \).

We can use the same relationships to efficiently graph log functions. Consider again the log function \( f(x) = \log_2 x \). The table below summarizes how we can use the graph of this function to graph other related function.

**Table 6.8:**

<table>
<thead>
<tr>
<th>Equation</th>
<th>Relationship to ( f(x) = \log_2 x )</th>
<th>Domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>( g(x) = \log_2(x - a) ), for ( a &gt; 0 )</td>
<td>Obtain a graph of ( g ) by shifting the graph of ( f ) ( a ) units to the right.</td>
<td>( x &gt; a )</td>
</tr>
<tr>
<td>( g(x) = \log_2(x + a) ) for ( a &gt; 0 )</td>
<td>Obtain a graph of ( g ) by shifting the graph of ( f ) ( a ) units to the left.</td>
<td>( x &gt; -a )</td>
</tr>
<tr>
<td>( g(x) = \log_2(x) + a ) for ( a &gt; 0 )</td>
<td>Obtain a graph of ( g ) by shifting the graph of ( f ) up ( a ) units.</td>
<td>( x &gt; 0 )</td>
</tr>
<tr>
<td>( g(x) = \log_2(x) - a ) for ( a &gt; 0 )</td>
<td>Obtain a graph of ( g ) by shifting the graph of ( f ) down ( a ) units.</td>
<td>( x &gt; 0 )</td>
</tr>
<tr>
<td>( g(x) = a \log_2(x) ) for ( a &gt; 0 )</td>
<td>Obtain a graph of ( g ) by vertically stretching the graph of ( f ) by a factor of ( a ).</td>
<td>( x &gt; 0 )</td>
</tr>
<tr>
<td>( g(x) = -a \log_2(x) ), for ( a &gt; 0 )</td>
<td>Obtain a graph of ( g ) by vertically stretching the graph of ( f ) by a factor of ( a ), and then reflecting the graph over the x-axis.</td>
<td>( x &gt; 0 )</td>
</tr>
<tr>
<td>( g(x) = \log_2(-x) )</td>
<td>Obtain a graph of ( g ) by reflecting the graph of ( f ) over the y-axis.</td>
<td>( x &lt; 0 )</td>
</tr>
</tbody>
</table>
Example 5: Graph the functions \( f(x) = \log_2(x), g(x) = \log_2(x) + 3 \), and \( h(x) = \log_2(x + 3) \)

Solution: The graph below shows these three functions together:

Notice that the location of the 3 in the equation makes a difference! When the 3 is added to \( \log_2 x \), the shift is vertical. When the 3 is added to the \( x \), the shift is horizontal. It is also important to remember that adding 3 to the \( x \) is a horizontal shift to the left. This makes sense if you consider the function value when \( x = -3 \):

\[ h(-3) = \log_2(-3 + 3) = \log_2 0 = \text{undefined} \]

This is the vertical asymptote! To graph these functions, we evaluated them for certain values of \( x \). But what if we want to know what the \( x \) value is for a particular \( y \) value? This means that we need to solve a logarithmic equation.

Solving Logarithmic Equations

In general, to solve an equation means to find the value(s) of the variable that makes the equation a true statement. To solve log equations, we have to think about what log \( \) means.

The equation \( \log_2 x = 5 \) means that \( 2^5 = x \). So the solution to the equation is \( x = 2^5 = 32 \).

Consider the equation \( \log_2 x = 5 \). What is the exponential form of this equation?

We can use this strategy to solve many logarithmic equations.

Example 6: Solve each equation for \( x \):

\[
\textbf{Table 6.9:}
\begin{align*}
a. \log_4 x &= 3 \\
b. \log_5 (x + 1) &= 2 \\
c. 1 + 2\log_3 (x - 5) &= 7 
\end{align*}
\]

Solution:

a. Writing the equation in exponential form gives us the solution: \( x = 4^3 = 64 \).

b. Writing the equation in exponential form gives us a new equation: \( 5^2 = x + 1 \). We can solve this equation for \( x \):
5^2 = x + 1
25 = x + 1
24 = x
x = 24

c. First we have to isolate the log expression:

1 + 2\log_3(x - 5) = 7
2\log_3(x - 5) = 6
\log_3(x - 5) = 3

Now we can solve the equation by rewriting it in exponential form:

\log_3(x - 5) = 3
3^3 = x - 5
27 = x - 5
32 = x
x = 32

We can also solve equations in which both sides of the equation contain logs. For example, consider the equation \(\log_2(3x - 1) = \log_2(5x - 7)\). Because the logarithms have the same base (2), the arguments of the log (the expressions 3x - 1 and 5x - 7) must be equal. So we can solve as follows:

\log_2(3x - 1) = \log_2(5x - 7)
3x - 1 = 5x - 7
+7 = +7
3x + 6 = 5x
-6 = -6
6 = 3x
3 = x
x = 3

Example 7: Solve for x: \(\log_2(9x) = \log_2(3x + 8)\)

Solution: The log equation implies that the expressions 9x and 3x + 8 are equal:

\textbf{Table 6.10:}

\[\log_2(9x) = \log_2(3x + 8)\]

9x = 3x + 8
Lesson Summary

In this lesson we have defined the logarithmic function as the inverse of the exponential function. When working with logarithms, it helps to keep in mind that a logarithm is an exponent. For example, \(3 = \log_2 8\) and \(2^3 = 8\) are two forms of the same numerical relationship among the three numbers 2, 3, and 8. The 2 is the base, the 3 is the exponent, and 8 is the \(3^{rd}\) power of 2.

Because logarithmic functions are the inverses of exponential functions, we can use our knowledge of exponential functions to graph logarithmic functions. You can graph a log function either by reflecting an exponential function over the line \(y = x\), or by evaluating the function and plotting points. In this lesson you learned how to graph parent graphs such as \(y = \log_2 x\) and \(y = \log_4 x\), as well as how to use these parent graphs to graph more complicated log functions. When graphing, it is important to keep in mind that logarithmic functions have restricted domains. Each graph will have a vertical asymptote.

We can also use our knowledge of exponential relationships to solve logarithmic equations. In this lesson we solved 2 kinds of logarithmic equations. First, we solved equations by rewriting the equations in exponential form. Second, we solved equations in which both sides of the equation contained a log to the same base. To solve these equations, we used the following rule:

\[
\log_b f(x) = \log_b g(x) \Rightarrow f(x) = g(x)
\]

Points to Think About

1. What methods can you use to graph logarithmic functions?
2. What methods can you use to solve logarithmic equations?
3. What forms of log equations can you solve using the methods in this lesson? Can you write an equation that cannot be solved using these methods?

Vocabulary

Argument

The expression inside a logarithmic expression. The argument represents the power in the exponential rela-
6.1. Logarithmic Functions

Asymptote
An asymptote is a line whose distance to a given curve tends to zero. An asymptote may or may not intersect its associated curve.

Domain
The domain of a function is the set of all values of the independent variable (x) for which the function is defined.

Evaluate
To evaluate a function is to identify a function value (y) for a given value of the independent variable (x).

Function
A function is a relation between a domain (set of x values) and range (set of y values) in which every element of the domain is paired with one and only one element of the range. A function that is one to one is a function in which every element of the domain is paired with exactly one y value.

Logarithm
The exponent of the power to which a base number must be raised to equal a given number.

Range
The range of a function is the set of all function values, or values of the dependent variable (y).
6.2 Properties of Logarithms

Learning objectives

• Use properties of logarithms to write logarithmic expressions in different forms.
• Evaluate common logarithms and natural logarithms.
• Use the change of base formula and a scientific calculator to find the values of logs with any bases.

Introduction

In the previous lesson we defined the logarithmic function as the inverse of an exponential function, and we evaluated log expressions in order to identify values of these functions. In this lesson we will work with more complicated log expressions. We will develop properties of logs that we can use to write a log expression as the sum or difference of several expressions, or to write several expressions as a single log expression. We will also work with logs with base 10 and base $e$, which are the bases most often used in applications of logarithmic functions.

Properties of Logarithms

Because a logarithm is an exponent, the properties of logs are the same as the properties of exponents. Here we will prove several important properties of logarithms.

Property 1: $\log_b(xy) = \log_b x + \log_b y$

Proof: Let $\log_b x = n$ and $\log_b y = m$.

Rewrite both log expressions in exponential form:
- $\log_b x = n \rightarrow b^n = x$
- $\log_b y = m \rightarrow b^m = y$

Now multiply $x$ and $y$: $xy = b^n \times b^m = b^{n+m}$

Therefore we have an exponential statement: $b^{n+m} = xy$.

The log form of the statement is: $\log_b xy = n + m$.

Now recall how we defined $n$ and $m$:
- $\log_b xy = n + m = \log_b x + \log_b y$.

Therefore:

$$\log_b(xy) = \log_b x + \log_b y$$

Property 2: $\log_b \left(\frac{x}{y}\right) = \log_b x - \log_b y$

We can prove property 2 analogously to the way we proved property 1.

Proof: Let $\log_b x = n$ and $\log_b y = m$.

Rewrite both log expressions in exponential form:
6.2. Properties of Logarithms

\[
\log_b x = n \rightarrow b^n = x
\]
\[
\log_b y = m \rightarrow b^m = y
\]
Now divide \( x \) by \( y \):
\[
\frac{x}{y} = \frac{b^n}{b^m} = b^{n-m}
\]
Therefore we have an exponential statement: \( b^{n-m} = \frac{x}{y} \).

The log form of the statement is: \( \log_b \left( \frac{x}{y} \right) = n - m \).

Now recall how we defined \( n \) and \( m \):
\[
\log_b \left( \frac{x}{y} \right) = n - m = \log_b x - \log_b y.
\]
Therefore:
\[
\log_b \left( \frac{x}{y} \right) = \log_b x - \log_b y
\]

**Property 3:** \( \log_b x^n = n \log_b x \)

The proof of the third property relies on another property of logs that we can derive by thinking about the definition of a log. Consider the expression \( \log_2 2^{13} \). What does this expression mean?

The exponential form of \( \log_2 2^{13} = ? \) is \( 2^? = 2^{13} \). Looking at the exponential form should convince you that the missing exponent is 13. That is, \( \log_2 2^{13} = 13 \). In general, \( \log_b b^n = n \). This property will be used in the proof of property 3.

**Proof (of Property 3):**

Let \( \log_b x = w \).

The exponential form of this log statement is \( b^w = x \).

If we raise both sides of this equation to the power of \( n \), we have \( (b^w)^n = x^n \).

Using the power property of exponents, this equation simplifies to \( b^{wn} = x^n \).

If two expressions are equal, then the logs of both expressions are equal:

\[
\log_b b^{wn} = \log_b x^n
\]

Now consider the value of the left side of the equation: \( \log_b b^{wn} \).

Earlier we had reasoned that in general: \( \log_b (b^w) = n \).

Following this reasoning, we have \( \log_b (b^{wn}) = wn \).

Previously, we had shown that \( \log_b x^n = \log_b x^n \).

By substitution, it follows that: \( \log_b (\frac{x}{y}) = wn \).

At this start of this proof, we had defined \( w: \log_b (x) = w \).

By substitution: \( \log_b (\frac{x}{y}) = (\log_b (x))^n \).

From the cumulative property of multiplication: \( \log_b (x^n) = n \log_b (x) \).

This completes the proof.

We can use these properties to rewrite log expressions.

**Expanding expressions**

Using the properties we have derived above, we can write a log expression as the sum or difference of simpler expressions. Consider the following examples:

1. \( \log_2 (8x) = \log_2 8 + \log_2 x = 3 + \log_2 x \)
2. \( \log_3 \left( \frac{x^2}{3} \right) = \log_3 x^2 - \log_3 3 = 2 \log_3 x - 1 \)
Using the log properties in this way is often referred to as "expanding". In the first example, expanding the log allowed us to simplify, as \( \log_2 8 = 3 \). Similarly, in the second example, we simplified using the log properties, and the fact that \( \log_3 3 = 1 \).

**Example 1:** Expand each expression:

<table>
<thead>
<tr>
<th>TABLE 6.11:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. ( \log_5 25x^2y )</td>
</tr>
</tbody>
</table>

**Solution:**

a. \( \log_5 25x^2y = \log_5 25 + \log_5 x^2 + \log_5 y = 2 + 2 \log_5 x + \log_5 y \)

b. 

<table>
<thead>
<tr>
<th>TABLE 6.12:</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \log_{10} \left( \frac{100x}{99} \right) )</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Just as we can write a single log expression as a sum and difference of expressions, we can also write expanded expressions as a single expression.

**Rewriting or Combining Logarithms into a Single Logarithm**

To combine logarithms by rewriting them as a single logarithm, we will use the same properties we used to expand logarithmic expressions. Consider the expression \( \log_6 8 + \log_6 27 \). Alone, each of these expressions does not have an integer value. The value of \( \log_6 8 \) is between 1 and 2; the value of \( \log_6 27 \) is also between 1 and 2. If we rewrite the expression, we get:

\[ \log_6 8 + \log_6 27 = \log_6 (8 \times 27) = \log_6 216 = 3 \]

We can also condense or rewrite logarithms with algebraic expressions and rewrite them as a single logarithmic expression. This will be useful later for solving logarithmic equations.

**Example 2:** Condense each expression into a single logarithm:

<table>
<thead>
<tr>
<th>TABLE 6.13:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. ( 2\log_3 x + \log_3 5x - \log_3 (x + 1) )</td>
</tr>
</tbody>
</table>

**Solution:**

a. \( 2\log_3 x + \log_3 5x - \log_3 (x + 1) = \log_3 x^2 + \log_3 5x - \log_3 (x + 1) \)

\[ = \log_3 (\frac{x^2(5x)}{x+1}) - \log_3 (x+1) \]

\[ = \log_3 \left( \frac{5x^3}{x+1} \right) \]
b. \( \log_2(x^2 - 4) - \log_2(x + 2) = \log_2 \left( \frac{x^2 - 4}{x + 2} \right) \\
= \log_2 \left( \frac{(x+2)(x-2)}{x + 2} \right) \\
= \log_2(x - 2) \\

It is important to keep in mind that a log expression may not be defined for certain values of \( x \). First, the argument of the log must be positive. For example, the expressions in example 2b above are not defined for \( x \leq 2 \) (which allows us to "divide out" \( x+2 \) without worrying about the condition \( x \neq -2 \)).

Second, the argument must be defined. For example, in example 2a above, the expression \( \left( \frac{5x^3}{x^2+1} \right) \) is undefined if \( x = -1 \).

The log properties apply to logs with any real base. Next we will examine logs with base 10 and base \( e \), which are the most commonly used bases for logs (though only one is actually called “common”).

**Common logarithms and natural logs**

A common logarithm is a log with base 10. We can evaluate a common log just as we evaluate any other log. A common log is usually written without a base. So when we see \( \log x \) without a base, it means the same thing as \( \log_{10} x \).

**Example 3:** Evaluate each log

<table>
<thead>
<tr>
<th>TABLE 6.14:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. ( \log 1 )</td>
</tr>
</tbody>
</table>

**Solution:**

\( \log \sqrt{10} = \frac{1}{2} \) because \( 10^{1/2} = \sqrt{10} \)

b. \( \log 10 = 1 \), as \( 10^1 = 10 \)

a. \( \log 1 = 0 \), as \( 10^0 = 1 \).

As noted in an earlier lesson, logarithms were introduced in order to simplify calculations. After Napier introduced the logarithm, another mathematician, Henry Briggs, proposed that the base of a logarithm be standardized as 10. Just as Napier had labored to compile tables of log values (though his version of the logarithm is somewhat different from what we use today), Briggs was the first person to publish a table of common logs. This was in 1617!

Until recently, tables of common logs were included in the back of math textbooks. Publishers discontinued this practice when scientific calculators became readily available. A scientific calculator will calculate the value of a common log to 8 or 9 digits. Most calculators have a button that says \( \text{LOG} \). For example, if you have TI graphing calculator, you can simply press \( \text{LOG} \), and then a number, and the calculator will give you a log value up to 8 or 9 decimal places. For example, if you enter \( \text{LOG}(7) \), the calculator returns 0.84509804. This means that \( 10^{0.84509804} \approx 7 \). If we want to judge the reasonableness of this value, we need to think about powers of 10. Because \( 10^1 = 10 \), \( \log(7) \) should be less than 1.

**Example 4:** For each log value, determine two integers between which the log value should lie. Then use a calculator to find the approximate value of the log.

<table>
<thead>
<tr>
<th>TABLE 6.15:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. ( \log 50 )</td>
</tr>
</tbody>
</table>
Solution:

a. \( \log 50 \)

The value of this log should be between 1 and 2, as \( 10^1 = 10 \), and \( 10^2 = 100 \).

Using a calculator, you should find that \( \log 50 \approx 1.698970004 \).

b. \( \log 818 \)

The value of this log should be between 2 and 3, as \( 10^2 = 100 \), and \( 10^3 = 1000 \).

Using a calculator, you should find that \( \log 818 \approx 2.912753304 \).

The calculators ability to produce log values is an example of the huge benefit that technology can provide. Only a few years ago, the calculations in the previous example would have each taken several minutes, while now they only take several seconds. While most people might not calculate log values in their every day lives, scientists and engineers are grateful to have such tools to make their work faster and more efficient.

Along with the LOG key on your calculator, you will find another logarithm key that says LN. This is the abbreviation for the natural log, the log with base \( e \). Natural logs are written using “ln” instead of “log.” That is, we write the expression \( \log_e x \) as \( \ln x \). How you evaluate a natural log depends on the argument of the log. You can evaluate some natural log expressions without a calculator. For example, \( \ln e = 1 \), as \( e^1 = e \). To evaluate other natural log expressions requires a calculator. Consider for example \( \ln 7 \). Recall that \( e \approx 2.7 \). This tells us that \( \ln 7 \) should be slightly less than 2, as \( (2.7)^2 = 7.29 \). Using a calculator, you should find that \( \ln 7 \approx 1.945910149 \).

**Example 5:** Find the value of each natural log.

<table>
<thead>
<tr>
<th>TABLE 6.16:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. ( \ln 100 )</td>
</tr>
</tbody>
</table>

**Solution:**

a. In 100 is between 4 and 5. You can estimate this by considering powers of 2.7, or powers of 3: \( 3^4 = 81 \), and \( 3^5 = 243 \).

Using a calculator, you should find that \( \ln 100 \approx 4.605171086 \).

b. Recall that a square root is the same as an exponent of 1/2. Therefore \( \ln \sqrt{e} = \ln(e^{1/2}) = 1/2 \).

You may have noticed that the common log and the natural log are the only log buttons on your calculator. We can use either the common log or the natural log to find the values of logs with other bases.

**Change of Base**

Consider the log expression \( \log_3 35 \). The value of this expression is approximately 3 because \( 3^3 = 27 \). In order to find a more exact value of \( \log_3 35 \), we can rewrite this expression in terms of a common log or natural log. Then we can use a calculator.

Let’s consider a general log expression, \( \log_b x = y \). This means that \( b^y = x \). Recall that if two expressions are equal, then the logs of the expressions are equal. We can use this fact, and the power property of logs, to write \( \log_b x \) in terms of common logs.

<table>
<thead>
<tr>
<th>TABLE 6.17:</th>
</tr>
</thead>
<tbody>
<tr>
<td>( b^y = x )</td>
</tr>
<tr>
<td>( \log b^y = \log x )</td>
</tr>
</tbody>
</table>
### 6.2. Properties of Logarithms

**Table 6.18:**

\[ b^y = x \Rightarrow \log_b x = y \]

**Table 6.19:**

| \( \Rightarrow y \log b = \log x \) | \( \Rightarrow y = \frac{\log x}{\log b} \) | Use the power property of logs |
| \( \Rightarrow \log_b x = \frac{\log x}{\log b} \) | Substitute \( \log_b x = y \) | Divide both sides by \( \log b \) |

The final equation, \( \log_b x = \frac{\log x}{\log b} \), is called the change of base formula. Notice that the proof did not rely on the fact that the base of the log is 10. We could have used a natural log. Thus another form of the change of base formula is \( \log b x = \frac{\ln x}{\ln b} \).

Note that we could have used a log with any base, but we use the common log and the natural log so that we can use a calculator to find the value of an expression. Consider again \( \log_3 35 \). If we use the change of base formula, and then a calculator, we find that

\[ \log_3 35 = \frac{\log 35}{\log 3} \approx 3.23621727. \]

**Example 6:** Estimate the value, and then use the change of base formula to find the value of \( \log_2 17 \).

**Solution:** \( \log_2 17 \) is close to 4 because \( 2^4 = 16 \) and \( 2^5 = 32 \). Using the change of base formula, we have \( \log_2 17 = \frac{\log 17}{\log 2} \). Using a calculator, you should find that the approximate value of this expression is 4.087462841.

**Lesson Summary**

In this lesson we have developed and used properties of logarithms, including a formula that allows us to calculate the value of a log expression with any base. Out of context, it may seem difficult to understand the value of these kind of calculations. However, as you will see in later lessons in this chapter, we can use exponential and logarithmic functions to model a variety of phenomena.

**To Think About**

1. Why is the common log called common? Why 10?
2. Why would you want to estimate the value of a log before using a calculator to find its exact value?
3. What kind of situations might be modeled with a logarithmic function?

**Vocabulary**

**Common logarithm**

A common logarithm is a log with base 10. The log is usually written without the base.

**Natural logarithm**

A natural log is a log with base \( e \). The natural log is written as \( \ln \).

**Scientific calculator**

A scientific calculator is an electronic, handheld calculator that will do calculations beyond the four operations.
(+, −, ×, ÷), such as square roots and logarithms. Graphing calculators will do scientific operations, as well
as graphing and equation solving operations.
6.3 Exponential and Logarithmic Models and Equations

Learning objectives

• Analyze data to determine if it can be represented by an exponential or logarithmic model.
• Use a graphing calculator to find an exponential or logarithmic model, and use a model to answer questions about a situation.
• Solve exponential and logarithmic equations using properties of exponents and logarithms.
• Find approximate solutions to equations using a graphing calculator.

Introduction

So far in this chapter we have evaluated exponential and logarithm expressions, and we have graphed exponential and logarithmic functions. In this lesson you will extend what you have learned in two ways. First, we will introduce the idea of modeling real phenomena with logarithmic and exponential functions. Second, we will solve logarithmic and exponential equations. While you have already solved some equations in previous lessons, now you will be able to solve more complicated equations. This lesson will provide you with further tools for the applications of logarithmic and exponential functions that will be the focus of the remainder of the chapter.

Exponential Models

Consider the following example: the population of a small town was 2,000 in the year 1950. The population increased over time, as shown by the values in the table:

<table>
<thead>
<tr>
<th>Year ( since 1950 )</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2000</td>
</tr>
<tr>
<td>5</td>
<td>2980</td>
</tr>
<tr>
<td>10</td>
<td>4450</td>
</tr>
<tr>
<td>20</td>
<td>9900</td>
</tr>
<tr>
<td>30</td>
<td>22,000</td>
</tr>
<tr>
<td>40</td>
<td>50,000</td>
</tr>
</tbody>
</table>

If you plot these data points, you will see that the growth pattern is non-linear:
In many situations, population growth can be modeled with an exponential function (this is because population grows as a percentage of the current population, i.e. 8% per year). In an upcoming lesson, you will learn how to create such models using information from a given situation. Here, we will focus on creating models using data and a graphing calculator.

The population data from the example above can be modeled with an exponential function, but the function is not unique. That is, there is more than one way to write a function to model this data. In the steps below you will see how to use a graphing calculator to find a function of the form $y = a(b^x)$ that fits the data in the table.

**Technology Note**

*Using a TI-83/84 graphing calculator to find an exponential function that best fits a set of data*

To enter data, press STAT, and then Option 1: Edit. Then enter the following into L1 and L2.

Now press the STAT button, and move to the right to the CALC menu. Scroll down to option 10: **ExpReg**. Press the ENTER button, and you will return to the home screen. You should see **ExpReg** on the screen. As long as the numbers are in L1 and L2, the calculator will proceed to find an exponential function to fit the data you listed in List L1 and List L2. You should see on the home screen the values for $a$ and $b$ in the exponential function (See figure below). Therefore the function $y = 1992.7(1.0837)^x$ is an approximate model for the data.

2. **Plotting the data and the equation**

To view plots of the data points and the equation on the same screen, do the following.

a. First, press Y= button and clear any equations.
You can type in the equation above, or to get the equation from the calculator, do the following:

b. Enter the above rounded-off equation in Y1, or use the following procedure to get the full equation from the calculator: put the cursor in Y1, press the VARS button, followed by 5: Statistics. Then go to the EQ menu, and press 1: ReqEQ. This should place the equation in Y1 (see figure below).

c. Now press the 2nd button, choose [Stat Plot] (above the Y+ button) and complete the items as shown in the figure below.

d. Now set your window. (Hint: use the range of the data to choose the window the figure below shows our choices.)

e. Press the GRAPH button and you will to see the function and the data points as shown in the figure below.

3. Comparing the real data with the modeled results
It looks as if the data points lie on the function. However, using the TRACE function you can determine how close the modeled points are to the real data. Press the TRACE button to enter the TRACE mode. Then press the right arrow to move from one data point to another. Do this until you land on the point with value Y=22000. To see the corresponding modeled value, press the up or down arrow. See the figure below. The modeled value is approximately 22197, which is quite close to the actual data. You can verify any of the other data points using the same method.
Now that we have the equation \( y = 1992.7(1.0837)^x \) to model the situation, we can estimate the population for any years that were not in the original data set. If we choose \( x \) values between 0 and 40, it is called **interpolation**. If we choose other \( x \) values outside of this domain, it is called **extrapolation**. Interpolation is, in a sense, a safer way of estimating population, because it is within the data points that we have, and does not require that we think about the end behavior of the function. For example, if we extrapolate to the year 1930, this means \( x = -20 \). The function value is 399. However, if the town was founded in 1940, then this data value does not make any sense. Similarly, if we extrapolate to the year 2000, we have \( x = 50 \). The function value is 110,711. However, if the towns pattern of population growth shifted (perhaps due to some economic change), this estimation could be highly inaccurate. As noted above, you will study exponential growth, as well as other exponential models, in the next two lessons. Now we turn to logarithmic models.

**Logarithmic Models**

Consider another example of population growth:

**Table 2**

<table>
<thead>
<tr>
<th>Year</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2000</td>
</tr>
<tr>
<td>5</td>
<td>4200</td>
</tr>
<tr>
<td>10</td>
<td>6500</td>
</tr>
<tr>
<td>20</td>
<td>8800</td>
</tr>
<tr>
<td>30</td>
<td>10500</td>
</tr>
<tr>
<td>40</td>
<td>12500</td>
</tr>
</tbody>
</table>

If we plot this data, we see that the growth is not quite linear, and it is not exponential either.

Just as we found an exponential model in the previous example, here we can find a logarithmic function to model this data. First enter the data in the table in L1 and L2. Then press STAT to get to the CALC menu. This time choose option 9: LnReg. You should get the function \( y = 930.4954615 + 2780.218173 \ln x \). If you view the graph and the
data points together, as described in the earlier Technology Note, you will see that the graph of the function does not touch the data points, but models the general trend of the data.

**Note about technology:** you can also do this using an Excel spreadsheet. Enter the data in a worksheet, and create a scatterplot by inserting a chart. After you create the chart, from the chart menu, choose “add trendline.” You will then be able to choose the type of function. Note that if you want to use a logarithmic function, the domain of your data set must be positive numbers. The chart menu will actually not allow you to choose a logarithmic trendline if your data include zero or negative x values. The image that follows is a chart with a logarithmic trendline.

![Image](chart_logarithmic_trendline.png)

**Solve Exponential Equations**

Given an exponential model of some phenomena, such as population growth, you may want to determine a particular input value that would produce a given function value. Let’s say that a function \( P(x) = 2000(1.05)^x \) models the population growth for a town. What if we want to know when the population reaches 20,000?

To answer this equation, we must solve the equation \( 2000(1.05)^x = 20,000 \). We can solve this equation by isolating the power \((1.05)^x\) and then using one of the log properties:

<table>
<thead>
<tr>
<th>Equation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( 2000(1.05)^x = 20,000 )</td>
<td>Divide both sides of the equation by 2000</td>
</tr>
<tr>
<td>((1.05)^x = 10 )</td>
<td>Take the common log of both sides</td>
</tr>
<tr>
<td>( \log(1.05)^x = \log 10 )</td>
<td>Use the power property of logs</td>
</tr>
<tr>
<td>( x\log(1.05) = \log 10 )</td>
<td>Evaluate ( \log 10 )</td>
</tr>
<tr>
<td>( x = \frac{1}{\log(1.05)} \approx 47 )</td>
<td>Divide both sides by ( \log(1.05) )</td>
</tr>
<tr>
<td></td>
<td>Use a calculator to estimate ( \log(1.05) )</td>
</tr>
</tbody>
</table>

We can use these same techniques to solve any exponential equation.

**Example 1:** Solve each exponential equation

<table>
<thead>
<tr>
<th>Equation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a. 2^x + 7 = 19 )</td>
<td>( b. 3^5x - 1 = 16 )</td>
</tr>
</tbody>
</table>

**Solution:**

<table>
<thead>
<tr>
<th>Equation</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a. 2^x + 7 = 19 )</td>
<td>( a. 2^x + 7 = 19 )</td>
</tr>
</tbody>
</table>
-7 - 7
2^x = 12
\log_2^2 = \log_12
x \cdot \log_2 = \log_12
x = \frac{\log_2^2}{\log_2} \approx 3.58

b. 3^{5x-1} = 16

\log_{3}^{3^{5x-1}} = \log_{16}
(5x - 1)\log_3 = \log_{16}
5x - 1 = \frac{\log_{16}}{\log_3}
5x = \frac{\log_{16}}{\log_3} + 1
x = \frac{\log_{16} + 1}{5}
x \approx 0.705

**Solve Logarithmic Equations**

In the previous lesson we solved two forms of log equations. Now we can solve more complicated equations, using our knowledge of log properties. For example, consider the equation \( \log_2 (x) + \log_2 (x - 2) = 3 \). We can solve this equation using a log property.

<table>
<thead>
<tr>
<th><strong>TABLE 6.24:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>( \log_2 (x) + \log_2 (x - 2) = 3 )</td>
</tr>
<tr>
<td>( \log_2 (x(x - 2)) = 3 )</td>
</tr>
<tr>
<td>( \log_2 (x^2 - 2x) = 3 )</td>
</tr>
<tr>
<td>( 2^3 = x^2 - 2x )</td>
</tr>
<tr>
<td>( x^2 - 2x - 8 = 0 )</td>
</tr>
<tr>
<td>( (x - 4)(x + 2) = 0 )</td>
</tr>
<tr>
<td>( x = -2, 4 )</td>
</tr>
</tbody>
</table>

The resulting quadratic has two solutions. However, only \( x = 4 \) is a solution to our original equation, as \( \log_2(-2) \) is undefined. We refer to \( x = -2 \) as an extraneous solution.

**Example 2:** Solve each equation

<table>
<thead>
<tr>
<th><strong>TABLE 6.25:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>a. ( \log (x + 2) + \log 3 = 2 )</td>
</tr>
<tr>
<td>b. ( \ln (x + 2) - \ln (x) = 1 )</td>
</tr>
</tbody>
</table>

**Solution:**

a. \( \log (x + 2) + \log 3 = 2 \)

**TABLE 6.26:**

| \( \log (3(x + 2)) = 2 \) |
| \( \log (3x + 6) = 2 \) |
| \( 10^2 = 3x + 6 \) |
| \( 100 = 3x + 6 \) |
| \( 3x = 94 \) |

\( \log_b^x + \log_b^y = \log_b^{} (xy) \)

\( \text{Simplify the expression } 3(x+2) \)

\( \text{Write the log expression in exponential form} \)

\( \text{Solve the linear equation} \)
6.3. Exponential and Logarithmic Models and Equations

<table>
<thead>
<tr>
<th>TABLE 6.26: (continued)</th>
</tr>
</thead>
<tbody>
<tr>
<td>log ((3(x + 2)) = 2)</td>
</tr>
<tr>
<td>(x = 94/3)</td>
</tr>
</tbody>
</table>

b. \(\ln (x + 2) - \ln (x) = 1\)

<table>
<thead>
<tr>
<th>TABLE 6.27:</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\ln \left( \frac{x + 2}{x} \right) = 1)</td>
</tr>
<tr>
<td>(e^{1} = \frac{x + 2}{x})</td>
</tr>
<tr>
<td>(ex = x + 2)</td>
</tr>
<tr>
<td>(ex - x = 2)</td>
</tr>
<tr>
<td>(x(e - 1) = 2)</td>
</tr>
<tr>
<td>(x = \frac{2}{e - 1})</td>
</tr>
</tbody>
</table>

The solution above is an exact solution. If we want a decimal approximation, we can use a calculator to find that \(x \approx 1.16\). We can also use a graphing calculator to find an approximate solution, as we did in lesson 2 with exponential equations. Consider again the equation \(\ln (x + 2) - \ln (x) = 1\). We can solve this equation by solving a system:

\[
\begin{align*}
y &= \ln(x + 2) - \ln(x) \\
y &= 1
\end{align*}
\]

If you graph the system on your graphing calculator, as we did in lesson 2, you should see that the curve and the horizontal line intersection at one point. Using the INTERSECT function on the CALC menu press the 2nd button followed by \([\text{CALC}]\), you should find that the \(x\) coordinate of the intersection point is approximately 1.16. This method will allow you to find approximate solutions for more complicated log equations.

**Example 3.** Use a graphing calculator to solve each equation:

<table>
<thead>
<tr>
<th>TABLE 6.28:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. (\log(5 - x) + 1 = \log x)</td>
</tr>
<tr>
<td>b. (\log_2(3x + 8) + 1 = \log_3 (10 - x))</td>
</tr>
</tbody>
</table>

**Solution:**

a. \(\log(5 - x) + 1 = \log x\)

The graphs of \(y = \log (5 - x) + 1\) and \(y = \log x\) intersect at \(x \approx 4.5454545\)

Therefore the solution of the equation is \(x \approx 4.54\).

b. \(\log_2 (3x + 8) + 1 = \log_3 (10 - x)\)

First, in order to graph the equations, you must rewrite them in terms of a common log or a natural log. The resulting equations are: \(y = \frac{\log(3x+8)}{\log 2} + 1\) and \(y = \frac{\log(10-x)}{\log 3}\). The graphs of these functions intersect at \(x \approx -1.87\). This value is the approximate solution to the equation.
Lesson Summary

This lesson has introduced the idea of modeling a situation using an exponential or logarithmic function. When a population or other quantity has a steep increase over time, it may be modeled with an exponential function. When a population has a steep increase, but then slower growth, it may be modeled with a logarithmic function. (In a later lesson you will learn about a third option.) We have also examined techniques of solving exponential and logarithmic equations, based on our knowledge of properties of logarithms. The key property to remember is the power property:

$$\log_b x^n = n \log_b x$$

Using this property allows us to turn an exponential function into a linear function, which we can then solve in order to solve the original exponential function.

In the remaining lessons in this chapter, you will learn about several different real phenomena that are modeled with exponential and logarithmic equations. In these lessons you will also use the techniques of equation solving learned here in order to answer questions about these phenomena.

To Think About

1. What kinds of situations might be modeled with exponential functions or logarithmic functions?
2. What restrictions are there on the domain and range of data if we use these functions as models?
3. When might an exponential or logarithmic equation have no solution?
4. What are the advantages and disadvantages of using a graphing calculator to solve exponential and logarithmic equations?

Vocabulary

Extraneous solution

An extraneous solution is a solution to an equation used to solve an initial equation that is not a solution to the initial equation. Extraneous solutions occur when solving certain kinds of equations, such as log equations, or square root equations.

Extrapolation

To extrapolate from data is to create new data points, or to predict, outside of the domain of the data set.

Interpolation

To interpolate is to create new data points, or to predict, within the domain of the data set, but for points not in the original data set.
In this lesson we will focus on a specific example of exponential growth: compounding of interest. We will begin with the case of simple interest, which refers to interest that is based only on the principal, or initial amount of an investment or loan. Then we will look at what it means for interest to compound. In the simplest terms, compounding means that interest accrues (you gain interest on an investment, or owe more on a loan) based on the principal you invested, as well as on interest you have already accrued. As you will soon see, compound interest is a case of exponential growth. In this lesson we will look at specific examples of compound interest, and we will write equations to model these specific situations.

Simple interest over time

As noted above, simple interest means that interest accrues based on the principal of an investment or loan. The simple interest is calculated as a percent of the principal. The formula for simple interest is, in fact, simple:

\[ I = P \times r \times t \]

where \( P \) represents the principal amount, \( r \) represents the interest rate, and \( t \) (expressed in decimal form) represents the amount of time the interest has been accruing. For example, say you borrow $2,000 from a family member, and you agree to pay 5% interest, and to pay the money back in 3 years. The interest you will owe will be \( 2000 \times 0.05 \times 3 = 300 \) dollars. This means that when you repay your loan, you will pay $2,300. Note that the interest you pay after 3 years is not 5% of the original loan, but 15%, as you paid 5% of $2,000 each year for 3 years.

Now let’s consider an example in which interest is compounded. Say that you invest $2,000 in a bank account, and it earns 5% interest annually. How much is in the account after 3 years?

In order to determine how much money is in the account after three years, we have to determine the amount of money in the account after each year. The table below shows the calculations for one, two, and three years of this investment:

<table>
<thead>
<tr>
<th>Year</th>
<th>Principal + interest</th>
</tr>
</thead>
<tbody>
<tr>
<td>After one year</td>
<td>( 2000 + 2000 \times 0.05 = 2000 + 100 = 2100 )</td>
</tr>
<tr>
<td>After 2 years</td>
<td>( 2100 + 2100 \times 0.05 = 2100 + 105 = 2205 )</td>
</tr>
<tr>
<td>After 3 years</td>
<td>( 2205 + 2205 \times 0.05 = 2205 + 110.25 = 2315.25 )</td>
</tr>
</tbody>
</table>

Therefore, after three years, you will have $2,315.25 in the account, which means that you will have earned $315.25 in interest. With simple interest, you would have earned $300 in interest. Compounding results in more interest because the principal on which the interest is calculated increased each year. For example, in the second year shown...
in the table above, you earned 5% of 2100, not 5% of 2000, as would be the case of simple interest. The main idea here is that compounding creates more interest because you are earning interest on interest, and not just on the principal.

But how much more?

You might look at the above example and say, its only $15.25. Remember that we have only looked at one example, and this example is a small one: in the grand scheme of investing, $2000 is a small amount of money, and we have only looked at the growth of the investment for a short period of time. For example, if you are saving for retirement, you could invest for a period of 30 years or more, and you might invest several thousand dollars each year. The formulas and methods for calculating retirement investments are more complicated than what we will do here. However, we can use the above example to derive a formula that will allow us to calculate compound interest for any number of years.

The compound interest formula

To derive the formula for compound interest, we need to look at a more general example. Lets return to the previous example, but instead of assuming the investment is $2000, let the principal of the investment be $P$ dollars. The key idea is that each year you have 100% of the principal, plus 5% of the previous balance. The table below shows the calculations of this more general investment.

<table>
<thead>
<tr>
<th>Year</th>
<th>Principal + interest</th>
<th>New principal</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$P + P(.05) = 1.00P + .05P = 1.05P$</td>
<td>1.05P</td>
</tr>
<tr>
<td>2</td>
<td>$(1.05)P + .05(1.05P) = 1.05P[1+.05] = 1.05P(1.05) = (1.05)^2P$</td>
<td>$(1.05)^2P$</td>
</tr>
<tr>
<td>3</td>
<td>$(1.05)^2P + .05(1.05)^2P = (1.05)^2P[1+.05] = (1.05)^3P$</td>
<td>$(1.05)^3P$</td>
</tr>
</tbody>
</table>

Notice that at the end of every year, the amount of money in the investment is a power of 1.05, times $P$, and that the power corresponds to the number of years. Given this pattern, you might hypothesize that after 4 years, the amount of money is $(1.05)^4P$.

We can generalize this pattern to a formula. As above, we let $P$ represent the principal of the investment. Now, let $t$ represent the number of years, and $r$ represent the interest rate. Keep in mind that $1.05 = 1+0.05$. So we can generalize:

$$A(t) = P(1 + r)^t$$

This function will allow us to calculate the amount of money in an investment, if the interest is compounded each year for $t$ years.

**Example 1:** Use the formula above to determine the amount of money in an investment after 20 years, if you invest $2000, and the interest rate is 5% compounded annually.

**Solution:**

$A(t) = P(1 + r)^t$

$A(20) = 2000(1.05)^{20}$

$A(20) \approx 5306.60$
The investment will be worth $5306.60.

In the above example, we found the value of this investment after a particular number of years. If we graph the function \( A(t) = 2000(1.05)^t \), we can see the values for any number of years.

![Graph of Compound Interest Function](image)

If you graph this function using a graphing calculator, you can determine the value of the investment by tracing along the function, or by pressing the TRACE button on your graphing calculator and then entering an \( x \) value. You can also choose an investment value you would like to reach, and then determine the number of years it would take to reach that amount. For example, how long will it take for the investment to reach $7,000?

As we did earlier in the chapter, we can find the intersection of the exponential function with the line \( y = 7000 \).

![Intersection of Exponential Function](image)

You can see from this figure that the line and the curve intersect at a little less than \( x = 26 \). Therefore it would take almost 26 years for the investment to reach $7000.

You can also solve for an exact value:

\[
\begin{align*}
2000(1.05)^t &= 7000 \\
(1.05)^t &= \frac{7000}{2000} \\
(1.05)^t &= 3.5 \\
\ln(1.05)^t &= \ln 3.5 \\
t \ln(1.05) &= \ln 3.5 \\
t &= \frac{\ln 3.5}{\ln 1.05} \approx 25.68
\end{align*}
\]

**Table 6.31:**

<table>
<thead>
<tr>
<th>Step</th>
<th>Calculation</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(2000(1.05)^t = 7000)</td>
<td>Divide both sides by 2000 and simplify the right side of the equation.</td>
</tr>
<tr>
<td>2</td>
<td>( (1.05)^t = \frac{7000}{2000} )</td>
<td>Take the ln of both sides (you can use any type of log, but ln or log base 10 will allow you to use a calculator.)</td>
</tr>
<tr>
<td>3</td>
<td>( (1.05)^t = 3.5 )</td>
<td>Use the power property of logs</td>
</tr>
<tr>
<td>4</td>
<td>( \ln(1.05)^t = \ln 3.5 )</td>
<td>Divide both sides by ln 1.05</td>
</tr>
<tr>
<td>5</td>
<td>( t \ln(1.05) = \ln 3.5 )</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>( t \approx 25.68 )</td>
<td></td>
</tr>
</tbody>
</table>

258
The examples we have seen so far are examples of annual compounding. In reality, interest is often compounded more frequently, for example, on a monthly basis. In this case, the interest rate is divided amongst the 12 months. The formula for calculating the balance of the account is then slightly different:

\[ A(t) = P \left(1 + \frac{r}{12}\right)^{12t} \]

Notice that the interest rate is divided by 12 because \(\frac{1}{12}\)th of the rate is applied each month. The variable \(t\) in the exponent is multiplied by 12 because the interest is calculated 12 times per year.

In general, if interest is compounded \(n\) times per year, the formula is:

\[ A(t) = P \left(1 + \frac{r}{n}\right)^{nt} \]

**Example 2:** Determine the value of each investment.

a. You invest $5000 in an account that gives 6% interest, compounded monthly. How much money do you have after 10 years?

b. You invest $10,000 in an account that gives 2.5% interest, compounded quarterly. How much money do you have after 10 years?

**Solution:**

a. $5000, invested for 10 years at 6% interest, compounded monthly. Monthly compounding means that interest is compounded twelve times per year. So in the equation, \(n = 12\).

\[ A(t) = P \left(1 + \frac{r}{n}\right)^{nt} \]
\[ A(10) = 5000 \left(1 + \frac{0.06}{12}\right)^{12 \cdot 10} \]
\[ A(10) = 5000 \left(1.005\right)^{120} \]
\[ A(10) \approx 9096.98 \]

The investment account balance is $9096.08 after 10 years.

b. $10,000, invested for 10 years at 2.5% interest, compounded quarterly. Quarterly compounding means that interest is compounded four times per year. So in the equation, \(n = 4\).

\[ A(t) = P \left(1 + \frac{r}{n}\right)^{nt} \]
\[ A(10) = 6000 \left(1 + \frac{0.025}{4}\right)^{4 \cdot 10} \]
\[ A(10) = 6000 \left(1.00625\right)^{40} \]
\[ A(10) \approx 12,830.30 \]

The investment account balance is $12,830.30 after 10 years.

In each example, the value of the investment after 10 years depends on three quantities: the principal of the investment, the number of compoundings per year, and the interest rate. Next we will look at an example of one investment, but we will vary each of these quantities.

**The power of compound interest**

Consider the investment in Example 1: $2000 was invested at an annual interest rate of 5%. We modeled this situation with the equation \(A(t) = 2000(1.05)^t\). We can use this equation to determine the amount of money in the
6.4. Compound Interest

Account after any number of years. As we saw above, the value of the account grows exponentially. You can see how fast the investment grows if we compare it to linear growth. For example, if the same investment earned simple interest, the value of the investment after \( t \) years could be modeled with the function \( B(t) = 2000 + 2000(0.05)t \). We can simplify this to be: \( B(t) = 100t + 2000 \). The exponential function and this linear function are shown here.

![Graph showing exponential vs. linear growth]

Notice that if we look at these investments over a long period of time (30 years are shown in the graph), the values look very close together for \( x \) values less than 10. For example, after 5 years, the compound interest investment is worth $2552.60, and the simple interest investment is worth $2500. But, after 20 years, the compound interest investment is worth $5306.60, and the simple interest investment is worth $4000. After 20 years, simple interest has doubled the amount of money, while compound interest has resulted in 2.65 times the amount of money.

The main idea here is that an exponential function grows faster than a linear one, which you can see from the graphs above. But what happens to the investment if we change the interest rate, or the number of times we compound per year?

**Example 3:** Compare the values of the investments shown in the table. If everything else is held constant (the principal, the number of times compounded per year, and time in years), how does the interest rate influence the value of the investment?

### Table 6.32:

<table>
<thead>
<tr>
<th>Principal</th>
<th>( r )</th>
<th>( n )</th>
<th>( t )</th>
</tr>
</thead>
<tbody>
<tr>
<td>$4000</td>
<td>0.02</td>
<td>12</td>
<td>8</td>
</tr>
<tr>
<td>$4000</td>
<td>0.05</td>
<td>12</td>
<td>8</td>
</tr>
<tr>
<td>$4000</td>
<td>0.10</td>
<td>12</td>
<td>8</td>
</tr>
<tr>
<td>$4000</td>
<td>0.15</td>
<td>12</td>
<td>8</td>
</tr>
<tr>
<td>$4000</td>
<td>0.22</td>
<td>12</td>
<td>8</td>
</tr>
</tbody>
</table>

**Solution:** Using the compound interest formula \( A(t) = P \left( 1 + \frac{r}{n} \right)^{nt} \), we can calculate the value of each investment. In all cases, we have \( A(8) = 4000 \left( 1 + \frac{0.05}{12} \right)^{12 \cdot 8} \).

### Table 6.33:

<table>
<thead>
<tr>
<th>Principal</th>
<th>( r )</th>
<th>( n )</th>
<th>( t )</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>$4000</td>
<td>0.02</td>
<td>12</td>
<td>8</td>
<td>$4693.42</td>
</tr>
<tr>
<td>$4000</td>
<td>0.05</td>
<td>12</td>
<td>8</td>
<td>$5962.34</td>
</tr>
<tr>
<td>$4000</td>
<td>0.10</td>
<td>12</td>
<td>8</td>
<td>$8872.70</td>
</tr>
<tr>
<td>$4000</td>
<td>0.15</td>
<td>12</td>
<td>8</td>
<td>$13182.05</td>
</tr>
<tr>
<td>$4000</td>
<td>0.22</td>
<td>12</td>
<td>8</td>
<td>$22882.11</td>
</tr>
</tbody>
</table>
As we increase the interest rate, the value of the investment increases. It is part of every day life to want to find the highest interest rate possible for a bank account (and the lowest possible rate for a loan!). Let’s look at just how fast the value of the account grows. Remember that each calculation in the table above started with \( A(8) = 4000 \left( 1 + \frac{r}{12} \right)^{12 \cdot 8} \). Notice that can be written as a function of \( r \), the interest rate. We can rewrite this as a function of \( x \), using \( x \) to represent the interest rate: \( f(x) = 4000 \left( 1 + \frac{x}{12} \right)^{96} \). The graph of this function is shown below:

Notice that while this function is not exponential, it does grow quite fast. As we increase the interest rate, the value of the account increases very quickly.

**Example 4:** Compare the values of the investments shown in the table. If everything else is held constant (principal, rate, and time), how does the compounding influence the value of the investment?

<table>
<thead>
<tr>
<th>Principal</th>
<th>( r )</th>
<th>( n ) (annual)</th>
<th>( t )</th>
<th>( A )</th>
</tr>
</thead>
<tbody>
<tr>
<td>$4,000</td>
<td>.05</td>
<td>1</td>
<td>8</td>
<td>$5909.82</td>
</tr>
<tr>
<td>$4,000</td>
<td>.05</td>
<td>4 (quarterly)</td>
<td>8</td>
<td>$5952.52</td>
</tr>
<tr>
<td>$4,000</td>
<td>.05</td>
<td>12 (monthly)</td>
<td>8</td>
<td>$5962.34</td>
</tr>
<tr>
<td>$4,000</td>
<td>.05</td>
<td>365 (daily)</td>
<td>8</td>
<td>$5967.14</td>
</tr>
<tr>
<td>$4,000</td>
<td>.05</td>
<td>8760 (hourly)</td>
<td>8</td>
<td>$5967.29</td>
</tr>
</tbody>
</table>

In contrast to the changing interest rate, in this example, increasing the number of compoundings per year does not seem to dramatically increase the value of the investment. We can see why this is the case if we look at the function \( A(8) = 4000 \left( 1 + \frac{.05}{n} \right)^{8n} \). We can use \( x \) to represent the number of compounding periods per year and rewrite it as a function of \( x \). A graph of the function \( f(x) = 4000 \left( 1 + \frac{.05}{x} \right)^{8x} \) is shown below:
The graph seems to indicate that the function has a horizontal asymptote at $6000. However, if we zoom in, we can see that the horizontal asymptote is closer to 5967.

What does this mean? This means that for the investment of $4000, at 5% interest, for 8 years, compounding more and more frequently will never result in more than about $5968.00.

Another way to say this is that the function $f(x) = 4000 \left(1 + \frac{0.05}{x}\right)^{8x}$ has a limit as $x$ approaches infinity. Next we will look at this kind of limit to define a special form of compounding.

**Continuous compounding**

Consider a hypothetical example: you invest $1.00, at 100% interest, for 1 year. For this situation, the amount of money you have at the end of the year depends on how often the interest is compounded:

$$F(t) = P \left(1 + \frac{r}{n}\right)^{nt}$$
$$F(t) = 1 \left(1 + \frac{1}{n}\right)^{ln}$$

$$A = \left(1 + \frac{1}{n}\right)^n$$

Now let’s consider different compoundings:

<table>
<thead>
<tr>
<th>Types of Compounding</th>
<th>n</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>Annual</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>Quarterly</td>
<td>4</td>
<td>2.44140625</td>
</tr>
<tr>
<td>Monthly</td>
<td>12</td>
<td>2.61303529022</td>
</tr>
<tr>
<td>Daily</td>
<td>365</td>
<td>2.71456748202</td>
</tr>
<tr>
<td>Hourly</td>
<td>8,760</td>
<td>2.71812669063</td>
</tr>
<tr>
<td>By the minute</td>
<td>525,600</td>
<td>2.7182792154</td>
</tr>
<tr>
<td>By the second</td>
<td>31,536,000</td>
<td>2.71828247254</td>
</tr>
</tbody>
</table>

The values of A in the table have a limit, which might look familiar: it’s the number e. In fact, one of the definitions of e is the value that $(1 + \frac{1}{n})^n$ approaches as $n$ increases without bound. Related to this is $e^x$ is the value that $(1 + \frac{x}{n})^n$ approaches as $n$ increases without bound.
Now we can define what is known as continuous compounding. If interest is compounded \( n \) times per year, the equation we use is: \( A(t) = P \left(1 + \frac{r}{n}\right)^{nt} \). We can also write the function as \( A(t) = P \left(\left(1 + \frac{r}{n}\right)^n\right)^t \). If we compound more and more often, we are looking at what happens to this function as \( n \) increases without bound. We now know \( e^x \) is the value that \( \left(1 + \frac{r}{n}\right)^n \) approaches as \( n \) increases without bound. So as \( n \) increases without bound, \( P \left(\left(1 + \frac{r}{n}\right)^n\right)^t \) approaches \( Pe^{rt} \).

The function \( A(t) = Pe^{rt} \) is the formula we use to calculate the amount of money when interest is continuously compounded, rather than interest that is compounded at discrete intervals, such as monthly or quarterly. For example, consider again the investment in Example 1 given earlier: what is the value of an investment after 20 years, if you invest $2000, and the interest rate is 5% compounded continuously?

\[
A(20) = 2000e^{0.05(20)} = 2000e^{1} = 5436.56
\]

Just as we did with the standard compound interest formula, we can also determine the time it takes for an account to reach a particular value if the interest is compounded continuously.

Example 5: How long will it take $2000 to grow to $25,000 in the previous example?

Solution: It will take about 50 and a half years:

\[
\begin{align*}
A(t) &= Pe^{rt} \\
25000 &= 2000e^{0.05t} \\
12.5 &= e^{0.05t} \\
\ln 12.5 &= 0.05t \\
\ln 12.5 &= \ln e^{0.05t} \\
\ln 12.5 &= 0.05t \\
t &= \frac{\ln 12.5}{0.05} \approx 50.5
\end{align*}
\]

Lesson Summary

In this lesson we have developed formulas to calculate the amount of money in a bank account or an investment when interest is compounded, either a discrete number of times per year, or compounded continuously. We have found the value of accounts or investments, and we have found the time it takes to reach a particular value. We have solved these problems algebraically and graphically, using our knowledge of functions in general, and logarithms in particular.

In general, the examples we have seen are conservative in the larger scheme of investing. Given all of the information available today about investments, you may look at the examples and think that the return on these investments seems low. For example, in the last example, 50 years probably seems like a long time to wait!

It is important to keep in mind that these calculations are based on an initial investment only. In reality, if you invest money long term, you will invest on a regular basis. For example, if an employer offers a retirement plan, you may invest a set amount of money from every paycheck, and your employer may contribute a set amount as well. As noted above, the calculations for the growth of a retirement investment are more complicated. However,
the exponential functions you have studied in this lesson are the basis for the calculations you would need to do. The examples here are meant to illustrate an application of exponential functions, and the power of compound interest.

To Think About

1. Why is compound interest modeled with an exponential function?
2. What is the difference between compounding and continuous compounding?
3. How are logarithms useful in solving compound interest problems?

Vocabulary

Accrue
To accrue is to increase in amount or value over time. If interest accrues on a bank account, you will have more money in your account. If interest accrues on a loan, you will owe more money to your lender.

Compound interest
Compound interest is interest based on a principal and on previous interest earned.

Continuous compounding
Interest that is based on continuous compounding is calculated according to the equation \( A(t) = Pe^{rt} \), where \( P \) is the principal, \( r \) is the interest rate, \( t \) is the length of the investment, and \( A \) is the value of the account or investment after \( t \) years.

Principal
The principal is the initial amount of an investment or a loan.

Simple interest
Simple interest is interest that is calculated as a percent of the principal, as a function of time.
6.5 Growth and Decay

Learning objectives

- Model situations using exponential and logistic functions.
- Solve problems involving these models, using your knowledge of properties of logarithms, and using a graphing calculator.

Introduction

In lesson 5 of this chapter, you learned about modeling phenomena with exponential and logarithmic functions. In the examples in lesson 5, you used a graphing calculator to find a regression equation that fits a given set of data. Here we will use algebraic techniques to develop models, and you will learn about another kind of function, the logistic function, that can be used to model growth.

Exponential growth

In general, if you have enough information about a situation, you can write an exponential function to model growth in the situation. Let’s start with a straightforward example:

Example 1: A social networking website is started by a group of 10 friends. They advertise their site before they launch, and membership grows fast: the membership doubles every day. At this rate, what will the membership be in a week? When will the membership reach 100,000?

Solution: To model this situation, let’s look at how the membership changes each day:

<table>
<thead>
<tr>
<th>Time (in days)</th>
<th>Membership</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>1</td>
<td>$2 \times 10 = 20$</td>
</tr>
<tr>
<td>2</td>
<td>$2 \times 2 \times 10 = 40$</td>
</tr>
<tr>
<td>3</td>
<td>$2 \times 2 \times 2 \times 10 = 80$</td>
</tr>
<tr>
<td>4</td>
<td>$2 \times 2 \times 2 \times 2 \times 10 = 160$</td>
</tr>
</tbody>
</table>

Notice that the membership on day $x$ is $10(2^x)$. Therefore we can model membership with the function $M(x) = 10(2^x)$. In seven days, the membership will be $M(7) = 10(2^7) = 1280$.

We can solve an exponential equation to find out when the membership will reach 100,000:

\[
10(2^x) = 100,000 \\
2^x = 10,000 \\
\log 2^x = \log 10,000 \\
x \log 2 = 4 \\
x = \frac{4}{\log 2} \approx 13.3
\]

At this rate, the membership will reach 100,000 in less than two weeks. This result may seem unreasonable. That’s very fast growth!
So let’s consider a slower rate of doubling. Let’s say that the membership doubles every 7 days.

**Table 6.39:**

<table>
<thead>
<tr>
<th>Time (in days)</th>
<th>Membership</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>7</td>
<td>$2 \times 10 = 20$</td>
</tr>
<tr>
<td>14</td>
<td>$2 \times 2 \times 10 = 40$</td>
</tr>
<tr>
<td>21</td>
<td>$2 \times 2 \times 2 \times 10 = 80$</td>
</tr>
<tr>
<td>28</td>
<td>$2 \times 2 \times 2 \times 2 \times 10 = 160$</td>
</tr>
</tbody>
</table>

We can no longer use the function $M(x) = 10(2^x)$. However, we can use this function to find another function to model this new situation. We will call this new function $N(x)$. Looking at one data point will help. Consider for example the fact that $N(21) = 10(2^3)$. This is the case because 21 days results in 3 periods of doubling. In order for $x = 21$ to produce $2^3$ in the equation, the exponent in the function must be $x/7$. So we have $N(x) = 10\left(2^{x/7}\right)$. Let’s verify that this equation makes sense for the data in the table:

| $M(0) = 10\left(2^0\right)$ | $= 10(1) = 10$ |
| $N(7) = 10\left(2^{7/7}\right)$ | $= 10(2) = 20$ |
| $N(14) = 10\left(2^{14/7}\right)$ | $= 10(2^2) = 10(4) = 40$ |
| $N(21) = 10\left(2^{21/7}\right)$ | $= 10(2^3) = 10(8) = 80$ |
| $N(28) = 10\left(2^{28/7}\right)$ | $= 10(2^4) = 10(16) = 160$ |

Notice that each $x$ value represents one more event of doubling, and in order for the function to have the correct power of 2, the exponent must be $(x/7)$.

With the new function $M(x) = 10\left(2^{x/7}\right)$, the membership doubles to 20 in one week, and reaches 100,000 in about 3 months:

$10\left(2^{x/7}\right) = 100,000$

$2^{x/7} = 100,000$

$log2^{x/7} = log100,000$

$x/7 log2 = 4$

$x log2 = 28$

$x = \frac{28}{log2} \approx 93$

The previous two examples of exponential growth have specifically been about doubling. We can also model a more general growth pattern with a more general growth model. While the graphing calculator produces a function of the form $y = a(b^t)$, population growth is often modeled with a function in which $e$ is the base. Let’s look at this kind of example:

The population of a town was 20,000 in 1990. Because of its proximity to technology companies, the population grew to 35,000 by the year 2000. If the growth continues at this rate, how long will it take for the population to reach 1 million?

The general form of the exponential growth model is much like the continuous compounding function you learned in the previous lesson. We can model exponential growth with a function of the form $P(t) = P_0e^{kt}$. The expression $P(t)$ represents the population after $t$ years, the coefficient $P_0$ represents the initial population, and $k$ is a growth constant that depends on the particular situation.

In the situation above, we know that $P_0 = 20,000$ and that $P(10) = 35,000$. We can use this information to find the value of $k$: 266
\[ P(t) = P_0 e^{kt} \]
\[ P(10) = 35000 = 20000 e^{10k} \]
\[ \frac{35000}{20000} = e^{10k} \]
\[ 1.75 = e^{10k} \]
\[ \ln 1.75 = 10k \ln e \]
\[ \ln 1.75 = 10k(1) \]
\[ \ln 1.75 = 10k \]
\[ k = \frac{\ln 1.75}{10} \approx 0.056 \]

Therefore we can model the population growth with the function \( P(t) = 20000e^{\ln 1.75 \cdot t} \). We can determine when the population will reach 1,000,000 by solving an equation, or using a graph.

Here is a solution using an equation:
\[ 1000000 = 20000e^{\ln 1.75 \cdot t} \]
\[ 50 = e^{\ln 1.75 \cdot t} \]
\[ \ln 50 = \ln \left( e^{\ln 1.75 \cdot t} \right) \]
\[ \ln 50 = \ln 1.75 \cdot t \ln e \]
\[ \ln 50 = \frac{\ln 1.75}{10} \cdot t(1) \]
\[ 10 \ln 50 = \ln 1.75 \cdot t \]
\[ t = \frac{10 \ln 50}{\ln 1.75} \approx 70 \]

At this rate, it would take about 70 years for the population to reach 1 million. Like the initial doubling example, the growth rate may seem very fast. In reality, a population that grows exponentially may not sustain its growth rate over time. Next we will look at a different kind of function that can be used to model growth of this kind.

**Logistic models**

Given that resources are limited, a population may slow down in its growth over time. Consider the last example, the town whose population increased from 20,000 to 35,000 in 10 years (from 1990 to 2000) and kept growing exponentially. If there are no more houses to be bought, or tracts of land to be developed, the population will not continue to grow exponentially. The table below shows the population of this town slowing down, though still growing:

<table>
<thead>
<tr>
<th>t (Years since 1990)</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20,000</td>
</tr>
<tr>
<td>10</td>
<td>35,000</td>
</tr>
<tr>
<td>15</td>
<td>38,000</td>
</tr>
<tr>
<td>20</td>
<td>40,000</td>
</tr>
</tbody>
</table>

As the population growth slows down, the population may approach what is called a **carrying capacity**, or an upper bound of the population. We can model this kind of growth using a logistic function, which is a function of the form \( f(x) = \frac{c}{1 + a(e^{-bx})} \).

The graph below shows an example of a logistic function. This kind of graph is often called an “s curve” because of its shape.
6.5. Growth and Decay

Notice that the graph shows slow growth, then fast growth, and then slow growth again, as the population or quantity in question approaches the carrying capacity. Logistics functions are used to model population growth, as well as other situations, such as the amount of medicine in a person’s system.

Given the population data above, we can use a graphing calculator to find a logistic function to model this situation. The details of this process are explained in the Technology Note in Lesson 5. As shown there, enter the data into L1 and L2. Then run a logistic regression. Press the STAT button, scroll right to CALC, and scroll down to B: Logistic.) An approximation of the logistic model for this data is: \[ f(x) = \frac{41042.38}{1 + 1.050e^{-0.178x}}. \] A graph of this function and the data is shown here.

Notice that the graph has a horizontal asymptote around 40,000. Looking at the equation, you should notice that the numerator is about 41,042. This value is in fact the horizontal asymptote, which represents the carrying capacity. We can understand why this is the carrying capacity if we consider the limit of the function as \( x \) increases without bound. As \( x \) gets larger and larger, \( e^{-0.178x} \) will get smaller and smaller. So \( 1.050e^{-0.178x} \) will get smaller. This means that the denominator of the function will get closer and closer to 1. Therefore:

\( (1 + 1.050e^{-0.178x}) \) approaches 1 as \( x \) increases without bound.

Therefore the limit of the function is (approximately) \( \frac{41042}{1} = 41042 \). This means that given the current growth, the model predicts that the population will not go beyond 41,042. This kind of growth is seen in actual populations, as well as other situations in which some quantity grows very fast and then slows down, or when a quantity steeply decreases, and then levels off. You will see work with more examples of logistic functions in the review questions.

**Exponential decay**

Just as a quantity can grow, or increase exponentially, we can model a decreasing quantity with an exponential function. This kind of situation is referred to as exponential decay. Perhaps the most common example of exponential decay is that of radioactive decay, which refers to the transformation of an atom of one type into an atom of a different type, when the nucleus of the atom loses energy. The rate of radioactive decay is usually measured in terms of “half-life,” or the time it takes for half of the atoms in a sample to decay. For example Carbon-14 is a radioactive isotope that is used in “carbon dating,” a method of determining the age of organic materials which include wood, leather, and bone. The half-life of Carbon-14 is 5730 years. This means that if we have a sample of Carbon-14, it will take 5730 years for half of the sample to decay. Then it will take another 5730 years for half of the remaining sample to decay, and so on.
We can model decay using the same form of equation we use to model growth, except that the exponent in the equation is negative: \( A(t) = A_0 e^{-kt} \). For example, say we have a sample of Carbon-14. How much time will pass before 75% of the original sample remains?

In order to find when the 75% of the original sample remains, we need to find the rate at which the sample decays. So we need to determine the decay constant \( k \) first. We can use the half-life of 5730 years to determine the value of \( k \):

\[
A(t) = A_0 e^{-kt} \\
\frac{1}{2} = 1 e^{-k \cdot 5730}
\]

\[
ln\left(\frac{1}{2}\right) = -k \cdot 5730
\]

\[
ln(1/2) = -5730k
\]

\[
k = \frac{ln2}{5730}
\]

Now we can determine when the amount of Carbon-14 remaining is 75% of the original:

\[
0.75 = 1 e^{\frac{ln2}{5730}t} \\
0.75 = 1 e^{\frac{ln2}{5730}t} \\
ln(0.75) = \frac{ln2}{5730}t
\]

\[
t = \frac{5730ln(0.75)}{-ln2} \approx 2378
\]

Therefore it would take about 2,378 years for 75% of the original sample to be remaining. In practice, scientists can approximate the age of an artifact using a process that relies on their knowledge of the half-life of Carbon-14, as well as the ratio of Carbon-14 to Carbon-12 (the most abundant, stable form of carbon) in an object. While the concept of half-life often is used in the context of radioactive decay, it is also used in other situations. In the review questions, you will see another common example, that of medicine in a person’s system.

Related to exponential decay is Newton’s Law of Cooling. The Law of Cooling allows us to determine the temperature of a cooling (or warming) object, based on the temperature of the surroundings and the time since the object entered the surroundings. The general form of the cooling function is \( T(x) = Ts + (T_0 - Ts) e^{-kx} \), where \( Ts \), is the surrounding temperature, \( T_0 \) is the initial temperature, and \( x \) represents the time since the object began cooling or warming.
The first graph shows a situation in which an object is cooling. The graph has a horizontal asymptote at \( y = 70 \). This tells us that the object is cooling to 70°F. The second graph has a horizontal asymptote at \( y = 70 \) as well, but in this situation, the object is warming up to 70°F.

We can use the general form of the function to answer questions about cooling (or warming) situations. Consider the following example: you are baking a casserole in a dish, and the oven is set to 325°F. You take the pan out of the oven and put it on a cooling rack in your kitchen which is 70°F, and after 10 minutes the pan has cooled to 300°F. How long will it take for the pan to cool to 200°F?

To answer this question, we first need to determine the rate at which the pan is cooling. We can use the general form of the equation and the information given in the problem to find the value of \( k \):

\[
T(x) = T_s + (T_0 - T_s)e^{-kx}
\]

\[
T(10) = 70 + 255e^{-10k} = 300
\]

\[
255e^{-10k} = 230
\]

\[
e^{-10k} = \frac{230}{255}
\]

\[
ln(e^{-10k}) = ln\left(\frac{230}{255}\right)
\]

\[
-10k = ln\left(\frac{230}{255}\right)
\]

\[
k = \frac{ln\left(\frac{230}{255}\right)}{-10} \approx 0.0103
\]

Now we can determine the amount of time it takes for the pan to cool to 200 degrees:

\[
T(x) = 70 + (255)e^{-0.0103x}
\]

\[
T(x) = 70 + (255)e^{-0.0103x}
\]

\[
200 = 70 + (255)e^{-0.0103x}
\]

\[
130 = (255)e^{-0.0103x}
\]

\[
\frac{130}{255} = e^{-0.0103x}
\]

\[
ln\left(\frac{130}{255}\right) = -0.0103x
\]

\[
x = \frac{ln\left(\frac{130}{255}\right)}{-0.0103} \approx 65
\]

It takes approximately 65 minutes to cool to the desired temperature. Therefore, in the given surroundings, it would take about an hour for the pan to cool to 200 degrees.

**Lesson Summary**

In this lesson we have developed exponential and logistic models to represent different phenomena. We have considered exponential growth, logistic growth, and exponential decay. After reading the examples in this lesson, you should be able to write a function to represent a given situation, to evaluate the function for a given value of \( x \), and to solve exponential equations in order to find values of \( x \), given values of the function. For example, in a situation of exponential population growth as a function of time, you should be able to determine the population at a particular time, and to determine the time it takes for the population to reach a given amount. You should be able to solve these kinds of problems by solving exponential equations, and by using graphing utilities, as we have done throughout the chapter.

**To Think About**

1. How can we use the same equation for exponential growth and decay?
2. What are the restrictions on domain and range for the examples in this lesson?
3. How can we use different equations to model the same situations?
Vocabulary

Carrying capacity
The supportable population of an organism, given the food, habitat, water and other necessities available within an ecosystem is known as the ecosystem’s carrying capacity for that organism.

Radioactive decay
Radioactive decay is the process in which an unstable atomic nucleus loses energy by emitting radiation in the form of particles or electromagnetic waves. This decay, or loss of energy, results in an atom of one type transforming to an atom of a different type. For example, Carbon-14 transforms into Nitrogen-14.

Half-life
The amount of time it takes for half of a given amount of a substance to decay. The half-life remains the same, no matter how much of the substance there is.

Isotope
Isotopes are any of two or more forms of a chemical element, having the same number of protons in the nucleus, or the same atomic number, but having different numbers of neutrons in the nucleus, or different atomic weights.
Learning objectives

- Work with the decibel system for measuring loudness of sound.
- Work with the Richter scale, which measures the magnitude of earthquakes.
- Work with pH values and concentrations of hydrogen ions.

Introduction

Because logarithms are related to exponential relationships, logarithms are useful for measuring phenomena that involve very large numbers or very small numbers. In this lesson you will learn about three situations in which a quantity is measured using logarithms. In each situation, a logarithm is used to simplify measurements of either very small numbers or very large numbers. We begin with measuring the intensity of sound.

Intensity of sound

Sound intensity is measured using a logarithmic scale. The intensity of a sound wave is measured in Watts per square meter, or W/m². Our hearing threshold (or the minimum intensity we can hear at a frequency of 1000 Hz), is 2.5 $10^{-12}$ W/m². The intensity of sound is often measured using the decibel (dB) system. We can think of this system as a function. The input of the function is the intensity of the sound, and the output is some number of decibels. The decibel is a dimensionless unit; however, because decibels are used in common and scientific discussions of sound, the values of the scale have become familiar to people.

We can calculate the decibel measure as follows:

$$\text{Intensity level (dB)} = 10 \log \left( \frac{\text{intensity of sound in W/m}^2}{0.937 \times 10^{-12} \text{W/m}^2} \right)$$

An intensity of $0.937 \times 10^{-12}$W/m² corresponds to 0 decibels:

$$10 \log \left( \frac{0.937 \times 10^{-12} \text{W/m}^2}{0.937 \times 10^{-12} \text{W/m}^2} \right) = 10 \log 1 = 10(0) = 0.$$ 

Note: The sound equivalent to 4 decibels is approximately the lowest sound that humans can hear.

If the intensity is ten times as large as the intensity corresponding to 0 decibels, the decibel level is 10:

$$10 \log \left( \frac{9.37 \times 10^{-11} \text{W/m}^2}{9.37 \times 10^{-12} \text{W/m}^2} \right) = 10 \log 10 = 10(1) = 10$$

If the intensity is 100 times as large as the intensity corresponding to 0 decibels, the decibel level is 20, and if the intensity is 1000 times as large, the decibel level is 30. (The scale is created this way in order to correspond to human hearing. We tend to underestimate intensity.) The threshold for pain caused by sound is 1 W/m². This intensity corresponds to about 120 decibels:

$$10 \log \left( \frac{1 \text{W/m}^2}{9.37 \times 10^{-12} \text{W/m}^2} \right) \approx 10(12) = 120$$
Many common phenomena are louder than this. For example, a jet can reach about 140 decibels, and concert can reach about 150 decibels. (Source: Ohanian, H.C. (1989) Physics. New York: W.W. Norton & Company.)

For ease of calculation, the equation is often simplified and 0.937 is rounded to 1 in the denominator of the argument of the logarithm.

### Table 6.42:

<table>
<thead>
<tr>
<th>Intensity level (dB)</th>

</table>

In the example below we will use this simplified equation to answer a question about decibels. (In the review exercises, you can also use this simplified equation).

**Example 1:** Verify that a sound of intensity 100 times that of a sound of 0 dB corresponds to 20 dB.

**Solution:**

\[
\text{dB} = 10\log\left(\frac{100 \times 10^{-12}}{10^{-12}}\right) = 10\log(100) = 10(2) = 20.
\]

### Intensity and magnitude of earthquakes

An earthquake occurs when energy is released from within the earth, often caused by movement along fault lines. An earthquake can be measured in terms of its intensity, or its magnitude. Intensity refers to the effect of the earthquake, which depends on location with respect to the epicenter of the quake. Intensity and magnitude are not the same thing.

As mentioned in lesson 3, the magnitude of an earthquake is measured using logarithms. In 1935, scientist Charles Richter developed this scale in order to compare the size of earthquakes. You can think of Richter scale as a function in which the input is the amplitude of a seismic wave, as measured by a seismograph, and the output is a magnitude. However, there is more than one way to calculate the magnitude of an earthquake because earthquakes produce two different kinds of waves that can be measured for amplitude. The calculations are further complicated by the need for a correction factor, which is a function of the distance between the epicenter and the location of the seismograph.

Given these complexities, seismologists may use different formulas, depending on the conditions of a specific earthquake. This is done so that the measurement of the magnitude of a specific earthquake is consistent with Richters original definition. (Source: [http://earthquake.usgs.gov/learning/topics/richter.php](http://earthquake.usgs.gov/learning/topics/richter.php))

Even without a specific formula, we can use the Richter scale to compare the size of earthquakes. Each point of increase in an earthquake’s magnitude represents a tenfold increase in the earthquakes measured amplitude. For example, the 1906 San Francisco earthquake had a magnitude of about 7.7. The 1989 Loma Prieta earthquake had a magnitude of about 6.9. (The epicenter of the quake was near Loma Prieta peak in the Santa Cruz mountains, south of San Francisco.) Because the Richter scale is logarithmic, this means that the 1906 quake was six times as strong as the 1989 quake. To determine this, we made a comparison between their relative amplitudes:

\[
\frac{10^{7.7}}{10^{6.9}} = 10^{7.7-6.9} = 10^8 \approx 6.3
\]

This kind of calculation explains why magnitudes are reported using a whole number and a decimal. In fact, a decimal difference makes a big difference in the size of the earthquake, as shown below and in the review exercises. Note that the strength of this earthquake was not time 10 times as large as the 1906 San Francisco earthquake because the increase from 6.9 to 7.7 was 0.8. If the 1906 earthquake had been a 7.9 on the Richter scale, then it would have been 10 times as strong as a 6.9 since this would have represented an increase of 1 in amplitude.

**Example 2:** An earthquake has a magnitude of 3.5. A second earthquake is 100 times as strong. What is the magnitude of the second earthquake?

Solution: The second earthquake is 100 times as strong as the earthquake of magnitude 3.5. This means that if the magnitude of the second earthquake is $x$, then:

$$\frac{10^4}{10^{3.5}} = 100$$
$$10^{x-3.5} = 100 = 10^2$$
$$x - 3.5 = 2$$
$$x = 5.5$$

So the magnitude of the second earthquake is 5.5. Since each point increase in magnitude on the Richter scale corresponds to a tenfold increase in strength of the earthquake, this solution also make sense.

The pH scale

If you have studied chemistry, you may have learned about acids and bases. An acid is a substance that produces hydrogen ions when added to water. A hydrogen ion is a positively charged atom of hydrogen, written as $H^+$. A base is a substance that produces hydroxide ions ($OH^-$) when added to water. Acids and bases play important roles in everyday life, including within the human body. For example, our stomachs produce acids in order to breakdown foods. However, for people who suffer from gastric reflux, acids travel up to and can damage the esophagus. Substances that are bases are often used in cleaners, but a strong base is dangerous: it can burn your skin.

To measure the concentration of an acid or a base in a substance, we use the pH scale, which was invented in the early 1900s by a Danish scientist named Soren Sorenson. The pH of a substance depends on the concentration of $H^+$, which is written with the symbol $[H^+]$.

$$pH = -\log [H^+]$$

(Note: concentration is usually measured in moles per liter. A mole is $6.02 \times 10^{23}$ units. Here, it would be $6.02 \times 10^{23}$ hydrogen ions.)

For example, the concentration of $H^+$ in stomach acid is about $1 \times 10^{-1}$ moles per liter. So the pH of stomach acid is $-\log (10^{-1}) = -(-1) = 1$. The pH scale ranges from 0 to 14. A substance with a low pH is an acid. A substance with a high pH is a base. A substance with a pH in the middle of the scale (at a 7) is considered to be neutral.
Example 3: The pH of ammonia is 11. What is the concentration of $H^+$?

Solution: $\text{pH} = -\log[H^+]$. If we substitute 11 for pH we can solve for $H^+$:

\[
\begin{align*}
11 & = -\log[H^+] \\
-11 & = \log[H^+] \\
10^{-11} & = 10^{\log[H^+]} \\
10^{-11} & = [H^+] \\
\end{align*}
\]

So the concentration of $H^+$ is $10^{-11}$ moles per liter.

Lesson Summary

In this lesson we have looked at three examples of logarithmic scales. In the case of the decibel system, using a logarithm has produced a simple way of categorizing the intensity of sound. The Richter scale allows us to compare earthquakes. And, the pH scale allows us to categorize acids and bases. In each case, a logarithm helps us work with large or small numbers, in order to more easily understand the quantities involved in certain real world phenomena.

To Think About

1. How are the decibel system and the Richter scale the same, and how are they different?
2. What other phenomena might be modeled using a logarithmic scale?
3. Two earthquakes of the same magnitude do not necessarily cause the same amount of destruction. How is that possible?
Vocabulary

Acid
An acid is a substance that produces hydrogen ions (H\(^+\)) when added to water.

Amplitude
The amplitude of a wave is the distance from its highest (or lowest) point to its center.

Base
A base is a substance that produces hydroxide ions (OH\(^-\)) when added to water.

Decibel
A decibel is a unitless measure of the intensity of sound.

Mole
\(6.02 \times 10^{23}\) units of a substance.

Seismograph
A seismograph is a device used to measure the amplitude of earthquakes.

Chapter 1

Factoring Polynomials and Polynomials Equations

1.1 Polynomial Equations in Factored Form

In Exercises 1-8, factor the common factor in the following polynomials.

1. \(3x^3 - 21x\)  
2. \(5x^6 + 15x^4\)  
3. \(4x^3 + 10x^2 - 2x\)  
4. \(-10x^6 + 12x^5 - 4x^4\)  
5. \(12xy + 24xy^2 + 36xy^3\)  
6. \(5a^3 - 7a\)  
7. \(45y^{12} + 30y^{10}\)  
8. \(16x^2z + 4x^3y\)

In Exercises 9-16, solve the following polynomial equations.

9. \(x(x + 12) = 0\)  
10. \((2x + 1)(2x - 1) = 0\)  
11. \((x - 5)(2x + 7)(3x - 4) = 0\)  
12. \(2x(x + 9)(7x - 20) = 0\)  
13. \(18y - 3y^2 = 0\)  
14. \(9x^2 = 27x\)  
15. \(4a^2 + a = 0\)  
16. \(3b^2 - 5b = 0\)

Answers

1. \(3x(x^2 - 7)\)  
2. \(5x^4(x^2 + 3)\)  
3. \(2x(2x^2 + 5x - 1)\)  
4. \(-2x^4(5x^2 - 6x + 2)\)  
5. \(12xy(1 + 2y + 3y^2)\)  
6. \(a(5a^2 - 7)\)  
7. \(15y^{10}(3y^2 + 2)\)  
8. \(4xy(4yz + x^2)\)  
9. \(x = 0, x = -12\)  
10. \(x = -\frac{1}{2}, x = \frac{1}{2}\)  
11. \(x = 5, x = -\frac{7}{2}, x = \frac{4}{3}\)  
12. \(x = 0, x = -9, x = \frac{20}{7}\)  
13. \(y = 0, y = 6\)  
14. \(x = 0, x = 3\)  
15. \(a = 0, a = -\frac{1}{3}\)  
16. \(b = 0, b = \frac{5}{3}\)
1.2 Factoring Quadratic Expressions and Solving Quadratic Equations by Factoring

In Exercises 1-24, factor the following quadratic polynomials.

1. \(x^2 + 10x + 9\)  
2. \(x^2 + 15x + 50\)  
3. \(x^2 + 10x + 21\)  
4. \(x^2 + 16x + 48\)  
5. \(x^2 - 11x + 24\)  
6. \(x^2 - 13x + 42\)  
7. \(x^2 - 14x + 33\)  
8. \(x^2 - 9x + 20\)  
9. \(x^2 + 5x - 14\)  
10. \(x^2 + 6x - 27\)  
11. \(x^2 + 7x - 78\)  
12. \(x^2 + 4x - 32\)  
13. \(x^2 - 12x - 45\)  
14. \(x^2 - 5x - 50\)  
15. \(x^2 - 3x - 40\)  
16. \(x^2 - x - 56\)  
17. \(-x^2 - 2x - 1\)  
18. \(-x^2 - 5x + 24\)  
19. \(-x^2 + 18x - 72\)  
20. \(-x^2 + 25x - 150\)  
21. \(x^2 + 21x + 108\)  
22. \(-x^2 + 11x - 30\)  
23. \(x^2 + 12x - 64\)  
24. \(x^2 - 17x - 60\)

In Exercises 25-28, solve.

25. \(x^2 + 12x - 28 = 0\)  
26. \(x^2 - 8x + 12 = 0\)  
27. \(x^2 - 9x - 36 = 0\)  
28. \(-x^2 = x - 20\)

29. The polynomial \(x^2 - 4x - 21\) has \((x + 3)\) as one of the factors. What is the other factor?

30. The polynomial \(x^2 - 2x + 1\) has \((x - 1)\) as one of the factors. What is the other factor?

31. The solutions to a quadratic equation are \(x = -2\) and \(x = 4\). What was the original equation in standard form with a leading coefficient of 1?

32. The solutions to a quadratic equation are \(x = \frac{2}{3}\) and \(x = \frac{1}{2}\). What was a possible original equation in standard form?

Answers

1. \((x + 1)(x + 9)\)  
2. \((x + 5)(x + 10)\)  
3. \((x + 7)(x + 3)\)  
4. \((x + 12)(x + 4)\)  
5. \((x - 3)(x - 8)\)  
6. \((x - 7)(x - 6)\)  
7. \((x - 11)(x - 3)\)  
8. \((x - 5)(x - 4)\)  
9. \((x - 2)(x + 7)\)  
10. \((x - 3)(x + 9)\)  
11. \((x - 6)(x + 13)\)  
12. \((x - 4)(x + 8)\)  
13. \((x - 15)(x + 3)\)  
14. \((x - 10)(x + 5)\)  
15. \((x - 8)(x + 5)\)  
16. \((x - 8)(x + 7)\)  
17. \(-(x + 1)(x + 1)\)  
18. \(-(x - 3)(x + 8)\)  
19. \(-(x - 6)(x - 12)\)  
20. \(-(x - 15)(x - 10)\)  
21. \((x + 9)(x + 12)\)  
22. \(-(x - 5)(x - 6)\)  
23. \((x - 4)(x + 16)\)  
24. \((x - 20)(x + 3)\)  
25. \(x = 14, x = 2\)  
26. \(x = 6, x = 2\)  
27. \(x = 12, x = -3\)  
28. \(x = 4, x = -5\)  
29. \((x - 7)\)  
30. \((x - 1)\)  
31. \(x^2 - 2x - 8 = 0\)  
32. \(6x^2 - 7x + 2 = 0\)
1.3 Factoring Special Products and Solving Quadratic Equations by Factoring

In Exercises 1-8, factor the following perfect square trinomials.

1. \( x^2 + 8x + 16 \)
2. \( x^2 - 18x + 81 \)
3. \( -x^2 + 24x - 144 \)
4. \( x^2 + 14x + 49 \)
5. \( 4x^2 - 4x + 1 \)
6. \( 25x^2 + 60x + 36 \)
7. \( -x^2 + 24x - 144 \)
8. \( x^2 + 14x + 49 \)

In Exercises 9-16, factor the following difference of squares.

9. \( x^2 - 4 \)
10. \( x^2 - 36 \)
11. \( -x^2 + 100 \)
12. \( x^2 - 400 \)
13. \( 9x^2 - 4 \)
14. \( 25x^2 - 49 \)
15. \( -36x^2 + 25 \)
16. \( 16x^2 - 81y^2 \)

In Exercises 17-19, factor the following sum or difference of cubes.

17. \( x^3 + 27 \)
18. \( 8x^3 - 1 \)
19. \( 64x^3 + 125y^3 \)

In Exercises 20-27, solve the following quadratic equation using factoring.

20. \( x^2 - 11x + 30 = 0 \)
21. \( x^2 + 4x = 21 \)
22. \( x^2 + 49 = 14x \)
23. \( x^2 - 64 = 0 \)
24. \( x^2 - 24x + 144 = 0 \)
25. \( 4x^2 - 25 = 0 \)
26. \( x^2 + 26x = -169 \)
27. \( -x^2 - 16x - 60 = 0 \)

28. The polynomial \( x^2 - 25 \) has a factor of \((x + 5)\). What is the other factor?
29. The polynomial \( 49x^2 - 100 \) has a factor of \((7x - 10)\). What is the other factor?
30. Factor \( 4x^2 + 9 \) completely, if possible. If it is not factorable, indicate it is prime.
31. Factor \( 121x^2 + 169 \) completely, if possible. If it is not factorable, indicate it is prime.

Answers

1. \((x + 4)^2\)
6. \((5x + 6)^2\)

16. \((4x + 9y)(4x - 9y)\)  
17. \((x + 3)(x^2 - 3x + 9)\)  
18. \((2x - 1)(4x^2 + 2x + 1)\)  
19. \((4x+5y)(16x^2 - 20xy + 25y^2)\)

20. \(x = 5, x = 6\)  
21. \(x = -7, x = 3\)  
22. \(x = 7 \text{ (double root)}\)  
23. \(x = -8, x = 8\)  
24. \(x = 12 \text{ (double root)}\)  
25. \(x = \frac{5}{2}, x = -\frac{5}{2}\)  
26. \(x = -13 \text{ (double root)}\)  
27. \(x = -10, x = 6\)  
28. \((x - 5)\)  
29. \((7x + 10)\)  
30. prime  
31. prime
1.4 Factoring Polynomials Completely and Solving Polynomial Equations by Factoring

In Exercises 1-4, factor completely.

1. \(2x^2 + 16x + 30\)  
2. \(-x^3 + 17x^2 - 70x\)  
3. \(2x^4 - 512\)  
4. \(12x^3 + 12x^2 + 3x\)

In Exercises 5-8, factor by grouping.

5. \(6x^2 - 9x + 10x - 15\)  
6. \(5x^2 - 35x + x - 7\)  
7. \(9x^2 - 9x - x + 1\)  
8. \(4x^2 + 32x - 5x - 40\)

In Exercises 9-12, factor the following quadratic binomials by grouping or trial and error.

9. \(4x^2 + 25x - 21\)  
10. \(6x^2 + 7x + 1\)  
11. \(4x^2 + 8x - 5\)  
12. \(3x^2 + 16x + 21\)

In Exercises 13-16, solve.

13. \(3x^2 + 24x + 36 = 0\)  
14. \(5x^2 - 45 = 0\)  
15. \(20x^2 - 39x + 18 = 0\)  
16. \(4x^2 + 12x + 9 = 0\)

Solve the following application problems:

17. One leg of a right triangle is 7 feet longer than the other leg. The hypotenuse is 13 feet. Find the dimensions of the right triangle.

18. A rectangle has sides of \((x + 2)\) and \((x - 1)\). What value of \(x\) gives an area of 108?

19. The product of two positive numbers is 120. Find the two numbers if one number is 7 more than the other.

20. Framing Warehouse offers a picture framing service. The cost for framing a picture is made up of two parts. The cost of glass is $1 per square foot. The cost of the frame is $2 per linear foot. If the frame is a square, what size picture can you get framed for $20?

Answers

1. \(2(x + 3)(x + 5)\)  
2. \(-x(x - 7)(x - 10)\)  
3. \(2(x - 4)(x + 4)(x^2 + 16)\)  
4. \(3x(2x + 1)^2\)  
5. \((2x - 3)(3x + 5)\)  
6. \((x - 7)(5x + 1)\)  
7. \((9x - 1)(x - 1)\)  
8. \((x + 8)(4x - 5)\)  
9. \((4x - 3)(x + 7)\)  
10. \((6x + 1)(x + 1)\)  
11. \((2x - 1)(2x + 5)\)  
12. \((x + 3)(3x + 7)\)  
13. \(x = -2, x = -6\)  
14. \(x = 3, x = -3\)  
15. \(x = \frac{3}{4}, x = \frac{6}{5}\)  
16. \(x = -\frac{3}{2}\) (double solution)  
17. leg 1 = 5 ft, leg 2 = 12 ft  
18. \(x = 10\)  
19. numbers are 8 and 15  
20. You can frame a 2 foot by 2 foot picture.
Chapter 2

Rational Functions

2.1 Variation Models

In Exercises 1-4, graph the following inverse variation relationships.

1. \( y = \frac{3}{x} \)  
2. \( y = \frac{10}{x} \)  
3. \( y = \frac{1}{4x} \)  
4. \( y = \frac{5}{6x} \)

5. A bottle of 150 vitamins costs $5.25. If the cost varies directly with the number of vitamins in the bottle, what should a bottle with 250 vitamins cost?

6. Wei received $55.35 in interest on the $1230 in her credit union account. If the interest varies directly with the amount deposited, how much would Wei receive for the same amount of time if she had $2000 in the account?

7. If \( z \) is inversely proportional to \( w \), and \( z = 81 \) when \( w = 9 \), find \( w \) when \( z = 24 \).

8. If \( y \) is inversely proportional to \( x \), and \( y = 2 \) when \( x = 8 \), find \( y \) when \( x = 12 \).

9. If \( a \) is inversely proportional to the square root of \( b \), and \( a = 32 \) when \( b = 9 \), find \( b \) when \( a = 6 \).

10. If \( w \) is inversely proportional to the square of \( u \) and \( w = 4 \) when \( u = 2 \), find \( w \) when \( u = 8 \).

11. The cost \( c \) of materials for a deck varies jointly with the width \( w \) and the length \( l \). If \( c = $470.40 \) when \( w = 12 \) and \( l = 16 \), find the cost when \( w = 10 \) and \( l = 25 \).

12. The value of real estate \( V \) varies jointly with the neighborhood index \( N \) and the square footage of the house \( S \). If \( V = $376,320 \) when \( N = 96 \) and \( S = 1600 \), find the value of a property with \( N = 83 \) and \( S = 2150 \).

13. The time to complete a project varies inversely with the number of employees. If 3 people can complete the project in 7 days, how long will it take 5 people?

14. The time needed to travel a certain distance varies inversely with the rate of speed. If it takes 8 hours to travel a certain distance at 36 miles per hour, how long will it take to travel the same distance at 60 miles per hour?

15. If \( x \) is proportional to \( y \) and inversely proportional to \( z \), and \( x = 2 \) when \( y = 10 \) and \( z = 25 \), find \( x \) when \( y = 8 \) and \( z = 35 \).
16. If \( a \) varies directly with \( b \) and inversely with the square of \( c \), and \( a = 10 \) when \( b = 5 \) and \( c = 2 \), find the value of \( a \) when \( b = 3 \) and \( c = 6 \).

17. The intensity of light is inversely proportional to the square of the distance between the light source and the object being illuminated. A light meter that is 10 meters from a light source registers 35 lux. What intensity would it register 25 meters from the light source?

18. Ohm’s Law states that current flowing in a wire is inversely proportional to the resistance of the wire. If the current is 2.5 Amperes when the resistance is 20 ohms, find the resistance when the current is 5 Amperes.

19. The volume of a gas varies directly to its temperature and inversely to its pressure. At 273 degrees Kelvin and pressure of 2 atmospheres, the volume of the gas is 24 liters. Find the volume of the gas when the temperature is 220 degrees Kelvin and the pressure is 1.2 atmospheres.

20. The volume of a square pyramid varies jointly as the height and the square of the length of the base. A square pyramid whose height is 4 inches and whose base has a side length of 3 inches has a volume of 12 cubic inches. Find the volume of a square pyramid that has a height 9 inches and whose base has a side length of 5 inches.

Answers

1. 

2. 

3. 

4.
5. $c = 0.035n; \quad $8.75
6. $i = 0.045d; \quad $90
7. $w = \frac{243}{8}
8. $y = \frac{4}{3}
9. $b = 256
10. $w = \frac{1}{4}
11. $c = 2.45wl; \quad $612.50
12. $V = 2.45NS; \quad $437, 202
13. $t = \frac{21}{c}; \quad $4.2 days
14. $t = \frac{288}{s}; \quad $4.8 hours
15. $x = \frac{8}{7}
16. $a = \frac{2}{3}
17. $I = 5.6 lux
18. $R = 10$ ohms
19. $V \approx 32.2$ L
20. $V \approx 75$ in$^3$
2.2 Graphs of Rational Functions

In Exercises 1-8, find all the vertical and horizontal asymptotes of the following rational functions.

1. \( f(x) = \frac{4}{x+2} \)  
2. \( f(x) = \frac{5x-1}{2x-6} \)  
3. \( f(x) = \frac{10}{x} \)  
4. \( f(x) = \frac{4x^2}{4x^2 + 1} \)  
5. \( f(x) = \frac{2x}{x^2 - 9} \)  
6. \( f(x) = \frac{3x^2}{x^2 - 4} \)  
7. \( f(x) = \frac{1}{x^2 + 4x + 3} \)  
8. \( f(x) = \frac{2x + 5}{x^2 - 2x - 8} \)

In Exercises 9-20, graph the following rational functions. Draw dashed vertical and horizontal lines on the graph to denote asymptotes.

9. \( f(x) = \frac{2}{x - 3} \)  
10. \( f(x) = \frac{3}{x^2} \)  
11. \( f(x) = \frac{x}{x - 1} \)  
12. \( f(x) = \frac{2x}{x + 1} \)  
13. \( f(x) = \frac{-1}{x^2 + 2} \)  
14. \( f(x) = \frac{x}{x^2 + 9} \)  
15. \( f(x) = \frac{x^2}{x^2 + 1} \)  
16. \( f(x) = \frac{1}{x^2 - 1} \)  
17. \( f(x) = \frac{2x}{x^2 - 9} \)  
18. \( f(x) = \frac{x^2}{x^2 - 16} \)  
19. \( f(x) = \frac{3}{x^2 - 4 + 4} \)  
20. \( f(x) = \frac{x}{x^2 - x - 6} \)

In Exercises 21-23, find the quantity labeled \( x \) in the following circuit.

21. \[ \text{Diagram of circuit with a resistor and a current meter} \]
22. \[ \text{Diagram of circuit with a resistor and a current meter} \]
23. \[ \text{Diagram of circuit with a resistor and a current meter} \]
Answers

1. vertical \( x = -2 \); horizontal \( y = 0 \)
2. vertical \( x = 3 \); horizontal \( y = \frac{5}{2} \)
3. vertical \( x = 0 \); horizontal \( y = 0 \)
4. no vertical; horizontal \( y = 1 \)
5. vertical \( x = 3 \), \( x = -3 \); horizontal \( y = 0 \)
6. vertical \( x = 2 \), \( x = -2 \); horizontal \( y = 3 \)
7. vertical \( x = -1 \), \( x = -3 \); horizontal \( y = 0 \)
8. vertical \( x = 4 \), \( x = -2 \); horizontal \( y = 0 \)

21. 18 V 

22. 12.5 ohms 

23. 2.5 Amperes
2.3 Rational Expressions

In Exercises 1-12, simplify each rational expression to lowest terms.

1. \( \frac{4}{2x - 8} \)  
2. \( \frac{x^2 + 2x}{x} \)  
3. \( \frac{9x + 3}{12x + 4} \)  
4. \( \frac{6x^2 + 2x}{4x} \)  
5. \( \frac{x - 2}{x^2 - 4x + 4} \)  
6. \( \frac{x^2 - 9}{5x + 15} \)  
7. \( \frac{x^2 + 6x + 8}{x^2 + 4x} \)  
8. \( \frac{2x^2 + 10x}{x^2 + 10x + 25} \)  
9. \( \frac{x^2 + 6x + 5}{x^2 - x - 2} \)  
10. \( \frac{x^2 - 16}{x^2 + 2x - 8} \)  
11. \( \frac{3x^2 + 3x - 18}{2x^2 + 5x - 3} \)  
12. \( \frac{x^3 + x^2 - 20x}{6x^2 + 6x - 120} \)

In Exercises 13-24, find the excluded values for each rational expression.

13. \( \frac{2}{x} \)  
14. \( \frac{4}{x + 2} \)  
15. \( \frac{2x - 1}{(x - 1)^2} \)  
16. \( \frac{3x + 1}{x^2 - 4} \)  
17. \( \frac{x^2}{x^2 + 9} \)  
18. \( \frac{2x^2 + 3x - 1}{x^2 - 3x - 28} \)  
19. \( \frac{5x^3 - 4}{x^2 + 3x} \)  
20. \( \frac{9}{x^3 + 11x^2 + 30x} \)  
21. \( \frac{4x - 1}{x^2 + 3x - 5} \)  
22. \( \frac{5x + 11}{3x^2 - 2x - 4} \)  
23. \( \frac{x^2 - 1}{2x^2 + x + 3} \)  
24. \( \frac{12}{x^2 + 6x + 1} \)

25. Suppose that two objects attract each other with a gravitational force of 20 Newtons. If the distance between the two objects is doubled, what is the new force of attraction between the two objects?

26. Suppose that two objects attract each other with a gravitational force of 36 Newtons. If the mass of both objects was doubled, and if the distance between the objects was doubled, then what would be the new force of attraction between the two objects?

27. A sphere with radius \( r \) has a volume of \( \frac{4}{3}\pi r^3 \) and a surface area of \( \frac{4}{3}\pi r^2 \). Find the ratio the surface area to the volume of a sphere.

28. The side of a cube is increased by a factor of two. Find the ratio of the old volume to the new volume.

29. The radius of a sphere is decreased by four units. Find the ratio of the old volume to the new volume.

Answers

1. \( \frac{2}{x - 4} \)  
2. \( x + 2, \ x \neq 0 \)  
3. \( \frac{3}{4}, \ x \neq -\frac{1}{3} \)  
4. \( \frac{3x + 1}{2}, \ x \neq 0 \)  
5. \( \frac{1}{x - 2} \)  
6. \( \frac{x - 3}{5}, \ x \neq -3 \)  
7. \( \frac{x + 2}{x}, \ x \neq -4 \)  
8. \( \frac{2x}{x + 5} \)  
9. \( \frac{x + 5}{x - 2}, \ x \neq -1 \)  
10. \( \frac{x - 4}{x - 2}, \ x \neq -4 \)  
11. \( \frac{3x - 6}{2x - 4}, \ x \neq -3 \)  
12. \( \frac{x}{6}, \ x \neq -5, \ x \neq 4 \)
13. $x = 0$
14. $x = -2$
15. $x = 1$
16. $x = 2, x = -2$
17. none
18. $x = -4, x = 7$
19. $x = 0, x = -3$
20. $x = 0, x = -5, x = -6$
21. $x \approx 1.19, x \approx -4.19$
22. $x \approx 1.54, x \approx -0.87$
23. none
24. $x \approx -0.17, x \approx -5.83$
25. 5 Newtons
26. 36 Newtons
27. $\frac{3}{r}$
28. $\frac{1}{8}$
29. $\frac{r^3}{(r - 3)^3}$
2.4 Multiplication and Division of Rational Expressions

In Exercises 1-20, perform the indicated operation and reduce the answer to lowest terms.

1. \( \frac{x^3}{2y^3} \cdot \frac{2y^2}{x} \)
2. \( 2xy \div \frac{2x^2}{y} \)
3. \( \frac{2x}{y^2} \cdot \frac{4y}{5x} \)
4. \( 2xy \cdot \frac{2y^2}{x^3} \)
5. \( \frac{4y^2 - 1}{y^2 - 9} \cdot \frac{y - 3}{2y - 1} \)
6. \( \frac{6ab}{a^2} \cdot \frac{a^3b}{3b^2} \)
7. \( \frac{x^2}{x - 1} \div \frac{x}{x^2 + x + 2} \)
8. \( \frac{33a^2}{5} \cdot \frac{20}{11a^3} \)
9. \( \frac{a^2 + 2ab + b^2}{ab^2 - a^2b} \div (a + b) \)
10. \( \frac{2x^2 + 2x - 24}{x^3 + 3x} \cdot \frac{x^2 + x - 6}{x + 4} \)
11. \( \frac{3 - x}{3x - 5} \div \frac{x^2 - 9}{2x^2 - 8x - 10} \)
12. \( \frac{x^2 - 25}{x + 3} \div (x - 5) \)
13. \( \frac{2x + 1}{2x - 1} \div \frac{4x^2 - 1}{1 - 2x} \)
14. \( \frac{x}{x - 5} \cdot \frac{x^2 - 8x + 15}{x^2 - 3x} \)
15. \( \frac{3x^2 + 5x - 12}{x^2 - 9} \div \frac{3x - 4}{3x + 4} \)
16. \( \frac{5x^2 + 16x + 3}{36x^2 - 25} \cdot (6x^2 + 5x) \)
17. \( \frac{x^2 + 7x + 10}{x^2 - 9} \cdot \frac{x^2 + 3x}{3x^2 + 4x - 4} \)
18. \( \frac{x^2 + x - 12}{x^2 + 4x + 4} \div \frac{x - 3}{x + 2} \)
19. \( \frac{x^4 - 16}{x^2 - 9} \div \frac{x + 4}{x - 3} \)
20. \( \frac{x^2 + 8x + 16}{7x^2 + 9x + 2} \cdot \frac{7x + 2}{x^2 + 4x} \)

21. Maria’s recipe asks for \( 2\frac{1}{2} \) times more flour than sugar. How many cups of flour should she mix in if she uses \( 3\frac{1}{3} \) cups of sugar?

22. George drives from San Diego to Los Angeles. On the return trip, he increases his driving speed by 15 miles per hour. In terms of his initial speed, by what factor is the driving speed decreased on the return trip?

23. Ohm’s Law states that in an electrical circuit \( I = \frac{V}{R_{tot}} \). The total resistance for resistors placed in parallel is \( \frac{1}{R_{tot}} = \frac{1}{R_1} + \frac{1}{R_2} \). Write the formula for the electric current in term of the component resistances: \( R_1 \) and \( R_2 \)
Answers

1. \( \frac{x^2}{y} \)
2. \( \frac{y^2}{x} \)
3. \( \frac{8}{5y} \)
4. \( \frac{4y^3}{x^2} \)
5. \( \frac{2y + 1}{y + 3} \)
6. \( 2a^2 \)
7. \( x^2 + 2x \)
8. \( -\frac{12}{a} \)
9. \( \frac{a + b}{ab^2 - a^2b} \)
10. \( \frac{2(x - 2)(x - 3)}{x} \) or \( \frac{2x^2 - 10x + 12}{x} \)
11. \( \frac{-2(x + 1)(x - 5)}{(x + 3)(3x - 5)} \) or \( \frac{-2x^2 + 8x + 10}{3x^2 + 4x - 15} \)
12. \( \frac{x + 5}{x + 3} \)
13. \( \frac{1}{1 - 2x} \)
14. \( 1 \)
15. \( \frac{3x + 4}{x - 3} \)
16. \( \frac{x(x + 3)(5x + 1)}{6x - 5} \) or \( \frac{5x^3 + 16x^2 + 3x}{6x - 5} \)
17. \( \frac{x(x + 5)}{(x - 3)(3x - 2)} \) or \( \frac{x^2 + 5x}{3x^2 - 11x + 6} \)
18. \( \frac{x + 4}{x + 2} \)
19. \( \frac{x - 4}{x + 3} \)
20. \( \frac{x + 4}{x(x + 1)} \) or \( \frac{x_4}{x^2 + x} \)
21. \( 8\frac{1}{3} \text{ cups} \)
22. \( \frac{s}{s + 15} \)
23. \( I = \frac{V}{R_1} + \frac{V}{R_2} \)
2.5 Addition and Subtraction of Rational Expressions

In Exercises 1-30, perform the indicated operation and simplify. Leave the denominator in factored form.

1. \( \frac{5}{24} - \frac{7}{24} \)
2. \( \frac{10}{21} + \frac{9}{35} \)
3. \( \frac{5}{2x+3} + \frac{3}{2x+3} \)
4. \( \frac{3x-1}{x+9} - \frac{4x+3}{x+9} \)
5. \( \frac{4x+7}{2x^2} - \frac{3x-4}{2x^2} \)
6. \( \frac{x^2}{x+5} - \frac{25}{x+5} \)
7. \( \frac{2x}{x-4} + \frac{x}{4-x} \)
8. \( \frac{10}{3x-1} - \frac{7}{1-3x} \)
9. \( \frac{5}{2x+3} - 3 \)
10. \( \frac{5x+1}{x+4} + 2 \)
11. \( \frac{1}{x} + \frac{2}{3x} \)
12. \( \frac{4}{5x^2} - \frac{2}{7x^3} \)
13. \( \frac{4x}{x+1} - \frac{2}{2(x+1)} \)
14. \( \frac{10}{x+5} + \frac{2}{x+2} \)
15. \( \frac{2x}{x-3} - \frac{3x}{x+4} \)
16. \( \frac{4x-3}{2x+1} + \frac{x+2}{x-9} \)
17. \( \frac{x^2}{x+4} - \frac{3x^2}{4x-1} \)
18. \( \frac{2}{5x+2} - \frac{x+1}{x^2} \)
19. \( \frac{x+4}{2x} + \frac{2}{9x} \)
20. \( \frac{5x+3}{x^2+x} + \frac{2x+1}{x} \)
21. \( \frac{4}{(x+1)(x-1)} - \frac{5}{(x+1)(x+2)} \)
22. \( \frac{2x}{(x+2)(3x-4)} + \frac{7x}{(3x-4)^2} \)
23. \( \frac{3x+5}{x(x-1)} - \frac{9x-1}{(x-1)^2} \)
24. \( \frac{1}{(x-2)(x-3)} + \frac{4}{(2x+5)(x-6)} \)
25. \( \frac{3x-2}{x-2} + \frac{1}{x^2-4x+4} \)
26. \( \frac{-x^2}{x^2-7x+6} + x - 4 \)
27. \( \frac{2x}{x^2+10x+25} - \frac{3x}{2x^2+7x-15} \)
28. \( \frac{1}{x^2-9} + \frac{2}{x^2+5x+6} \)
29. \( \frac{-x+4}{2x^2-x-15} + \frac{x}{4x^2+8x-5} \)
30. \( \frac{4}{9x^2-49} - \frac{1}{3x^2+5x-28} \)

31. One number is 8 times more than another. The difference in their reciprocals is \( \frac{21}{20} \). Find the two numbers.

32. One number is 5 less than another. The sum of their reciprocals is \( \frac{13}{36} \). Find the two numbers.
33. A pipe can fill a tank full of oil in 4 hours and another pipe can empty the tank in 8 hours. If the valves to both pipes are open, how long would it take to fill the tank?

34. Stefan could wash the cars by himself in 6 hours and Misha could wash the cars by himself in 5 hours. Stefan starts washing the cars by himself, but he needs to go to his football game after 2.5 hours. Misha continues the task. How long did it take Misha to finish washing the cars?

35. Amanda and her sister Chyna are shoveling snow to clear their driveway. Amanda can clear the snow by herself in three hours and Chyna can clear the snow by herself in four hours. After Amanda has been working by herself for one hour, Chyna joins her and they finish the job together. How long does it take to clear the snow from the driveway?

36. At a soda bottling plant one bottling machine can fulfill the daily quota in 10 hours, and a second machine can fill the daily quota in 14 hours. The two machines start working together but after four hours the slower machine broke and the faster machine had to complete the job by itself. How many hours does the fast machine works by itself?

Answers

1. $- \frac{1}{12}$

24. $\frac{6x^2 - 27x - 6}{(x - 2)(x - 3)(2x + 5)(x - 6)}$
25. $\frac{3x^2 - 8x + 5}{(x - 2)^2}$
26. $\frac{x^3 - 12x^2 - 34x - 24}{(x - 6)(x - 1)}$
27. $\frac{x^2 - 21x}{(2x - 3)(x + 5)^2}$
28. $\frac{3x - 4}{(x - 3)(x + 3)(x + 2)}$
29. $\frac{-x^2 + 6x - 4}{(2x + 5)(x - 3)(2x - 1)}$
30. $\frac{x + 9}{(3x + 7)(3x - 7)(x + 4)}$

31. The numbers are $\frac{5}{6}$ and $\frac{20}{3}$.

32. The numbers are 4 and 9 or the numbers are $- \frac{45}{13}$ and $\frac{20}{13}$.
33. 8 hours (Hint: How might we indicate one pipe filling the tank while the other is drinking the tank? What might \( \frac{t}{4} - \frac{t}{8} = 1 \) mean?)

34. 2 hours and 55 minutes or \( 2\frac{11}{12} \) hours that Misha worked alone to finish washing cars. (Hint: What portion of the job did Stefan complete before leaving? What might \( t = 1 - \frac{2.5}{6} \) mean?)

35. 1\(\frac{1}{4}\) hours, which is approximately 1 hour and 9 minutes. (Hint: What portion of the job did Amanda complete by herself? What might \( \frac{t}{3} + \frac{t}{4} = 1 - \frac{1}{3} \) mean?)

36. 3\(\frac{1}{2}\) hours, which is approximately 3 hours and 9 minutes. (Hint: What portion of the job did each machine complete when they were both operating together? What might \( \frac{t}{10} = 1 - \frac{4}{14} - \frac{4}{10} \) mean?)
### 2.6 Complex Rational Fractions

Simplify the following:

1. \( \frac{1 + \frac{1}{x}}{1 - \frac{1}{x^2}} \)
2. \( \frac{1}{2 + \frac{1}{y}} - \frac{1}{y} \)
3. \( \frac{a - 2}{4} - \frac{1}{a} \)
4. \( \frac{1}{a^2} - \frac{1}{a^2 + 1} \)
5. \( \frac{1}{b + \frac{1}{4}} - \frac{1}{b^2 - 1} \)
6. \( \frac{2 - \frac{4}{x + 2}}{5 - \frac{10}{x + 2}} \)
7. \( \frac{a - 1}{\frac{3}{a} - \frac{3}{a}} \)
8. \( \frac{4 + \frac{12}{2x - 3}}{5 + \frac{15}{2x - 3}} \)
9. \( \frac{2a - 3 + 2}{2a - 3 - 4} \)
10. \( \frac{-5}{b - 5} - \frac{3}{b + 5} \)
11. \( \frac{-4}{a^2 - 2} - \frac{1}{a} \)
12. \( \frac{\frac{2a}{x} - \frac{3}{a}}{\frac{1}{a} - \frac{4}{x}} \)
13. \( \frac{3}{x^9} - \frac{x}{x^2} \)
14. \( \frac{x}{3x^2 - 2} \)
15. \( \frac{-6}{2a - 3 - 4} \)
16. \( \frac{x}{9x^2 - 4} \)
17. \( \frac{x}{a - b} \)
18. \( \frac{\frac{3}{x} + 2}{\frac{3x + 10}{x} - \frac{8}{x + 10}} \)
19. \( \frac{\frac{2}{x} - \frac{3}{x - 4}}{\frac{3x + 10}{x} - \frac{8}{x + 10}} \)
20. \( \frac{\frac{2}{x} - \frac{3}{x - 4}}{\frac{3x + 10}{x} - \frac{8}{x + 10}} \)

#### Answers

1. \( \frac{x}{x - 1} \)
2. \( \frac{1 - y}{y} \)
3. \( \frac{-a}{a + 2} \)
4. \( \frac{5 - a}{a} \)
5. \( \frac{-a - 1}{a + 1} \)
6. \( \frac{b^2 + 2b^2 - b - 2}{8b} \)
7. \( \frac{2}{5} \)
8. \( \frac{4}{5} \)
9. \( \frac{-1}{2} \)
10. \( \frac{-1}{2} \)
11. \( \frac{x^2 - x - 1}{x^2 + x + 1} \)
12. \( \frac{2a^2 - 3a + 3}{-4a^2 - 2a} \)
13. \( \frac{x}{3} \)
14. \( \frac{x}{3} \)
15. \( \frac{4b(a - b)}{a} \)
16. \( \frac{x}{x - 1} \)
17. \( \frac{x - 5}{x + 9} \)
18. \( \frac{(x - 3)(x + 5)}{4x^2 - 5x + 4} \)
19. \( \frac{1}{3x + 8} \)
20. \( \frac{1}{x + 4} \)
21. \( \frac{x - 2}{x + 2} \)
22. \( \frac{x - 7}{x + 5} \)
2.7 Solutions of Rational Equations

In Exercises 1-18, solve the following equations.

1. \( \frac{2x + 1}{4} = \frac{x - 3}{10} \)
2. \( \frac{4x}{x + 2} = \frac{5}{9} \)
3. \( \frac{5}{3x - 4} = \frac{2}{x + 1} \)
4. \( \frac{7x}{x - 1} = \frac{x + 3}{x} \)
5. \( \frac{2}{x + 3} - \frac{1}{x + 4} = 0 \)
6. \( \frac{3x^2 + 2x - 1}{x^2 - 1} = -2 \)
7. \( x + \frac{1}{x} = 2 \)
8. \( -3 + \frac{1}{x + 1} = -\frac{9}{4} \)
9. \( \frac{1}{x} - \frac{x}{x - 2} = 2 \)
10. \( \frac{3}{2x - 1} + \frac{2}{x + 4} = 2 \)
11. \( \frac{2x}{x - 1} - \frac{x}{3x + 4} = 3 \)
12. \( \frac{x + 1}{x - 1} + \frac{x - 4}{x + 4} = 3 \)
13. \( \frac{x}{x - 2} + \frac{x}{x + 3} = \frac{1}{x^2 + x - 6} \)
14. \( \frac{2}{x^2 + 4x + 3} = 2 + \frac{x - 2}{x + 3} \)
15. \( \frac{1}{x + 5} - \frac{1}{x - 5} = \frac{1 - x}{x + 5} \)
16. \( \frac{x}{x^2 - 36} + \frac{1}{x - 6} = \frac{1}{x + 6} \)
17. \( \frac{2x}{3x + 3} - \frac{1}{4x + 4} = \frac{2}{x + 1} \)
18. \( \frac{-x}{x - 2} + \frac{3x - 1}{x + 4} = \frac{1}{x^2 + 2x - 8} \)

19. Juan jogs a certain distance and then walks a certain distance. When he jogs he averages 7 miles/hour. When he walks, he averages 3.5 miles/hour. If he walks and jogs a total of 6 miles in a total of 1 hour and 12 minutes, how far does he jog and how far does he walk?

20. A boat travels 60 miles downstream in the same time as it takes it to travel 40 miles upstream. The boat’s speed in still water is 20 miles/hour. Find the speed of the current.

21. Paul leaves San Diego driving at 50 miles/hour. Two hours later, his mother realizes that he forgot something and drives in the same direction at 70 miles/hour. How long does it take her to catch up to Paul?

22. On a trip, an airplane flies at a steady speed against the wind. On the return trip the airplane flies with the wind. The airplane takes the same amount of time to fly 300 miles against the wind as it takes to fly 420 miles with the wind. The wind is blowing at 30 miles/hour. What is the speed of the airplane when there is no wind?

23. A debt of $420 is shared equally by a group of friends. When five of the friends decide not to pay, the share of the other friends goes up by $25. How many friends were in the group originally?

24. A non-profit organization collected $2250 in equal donations from their members to share the cost of improving a park. If there were thirty more members, then each member could contribute $20 less. How many members does this organization have?
Answers

1. \( x = -\frac{11}{8} \)

7. \( x = 1 \)

13. \( x = -1; x = \frac{1}{2} \)

2. \( x = \frac{10}{31} \)

8. \( x = \frac{1}{3} \)

14. \( x = -2; x = -\frac{1}{3} \)

3. \( x = 13 \)

9. \( x = 1, x = \frac{2}{3} \)

15. \( x \approx -1.74, x \approx 6.74 \)

4. \( x = \frac{1 \pm i\sqrt{17}}{6} \)

10. \( x \approx -3.17, x \approx 1.42 \)

16. \( x = -12 \)

5. \( x = -5 \)

11. \( x \approx -1.14, x \approx 2.64 \)

17. \( x = \frac{27}{8} \)

6. \( x = \frac{3}{5} \)

12. \( x \approx -10.84, x \approx 1.84 \)

18. \( x \approx 0.92, x \approx 5.41 \)

19. jogs 3.6 miles and walks 2.4 miles (Hint: How do distance and speed related to time?)

20. 4 miles/hour (Hint: How does the current affect the boat’s speed upstream? Downstream?)

21. 5 hours (Hint: Who travels for a longer time?)

22. 180 miles/hour (How is the effective of speed of the plane change when flying with the wind? Against the wind?)

23. 12 friends (Hint: Would the original group of friends have paid a higher or lower portion of the debt? By how much did the portion of the share for each person change as a result of five friends not paying?)

24. 45 members (Hint: Does having more members in the organization increase or decrease the amount each person would need to contribute? By how much?)
Chapter 3

Radical Functions

3.1 Graphs of Square Root Functions

In Exercises 1-4, graph the functions on the same coordinate axes.

1. \( f(x) = \sqrt{x}, f(x) = 2.5\sqrt{x}, \) and \( f(x) = -2.5\sqrt{x}. \)
2. \( f(x) = \sqrt{x}, f(x) = 0.3\sqrt{x}, \) and \( f(x) = 0.6\sqrt{x}. \)
3. \( f(x) = \sqrt{x}, f(x) = \sqrt{x-5}, \) and \( f(x) = \sqrt{x+5}. \)
4. \( f(x) = \sqrt{x}, f(x) = \sqrt{x}+8, \) and \( f(x) = \sqrt{x}-8. \)

In Exercises 5-13, graph the functions.

5. \( f(x) = \sqrt{2x-1} \)
6. \( f(x) = \sqrt{4x+4} \)
7. \( f(x) = \sqrt{5-x} \)
8. \( f(x) = 2\sqrt{x}+5 \)
9. \( f(x) = 3-\sqrt{x} \)
10. \( f(x) = 4+2\sqrt{x} \)
11. \( f(x) = 2\sqrt{2x+3}+1 \)
12. \( f(x) = 4+2\sqrt{2-x} \)
13. \( f(x) = \sqrt{x+1}-\sqrt{4x-5} \)

14. The acceleration of gravity can also given in feet per second squared. It is \( g = 32 \text{ ft/s}^2 \) at sea level. Graph the period of a pendulum with respect to its length in feet. For what length in feet will the period of a pendulum be two seconds?

15. The acceleration of gravity on the Moon is \( 1.6 \text{ m/s}^2 \). Graph the period of a pendulum on the Moon with respect to its length in meters. For what length, in meters, will the period of a pendulum be 10 seconds.

16. The acceleration of gravity on Mars is \( 3.69 \text{ m/s}^2 \). Graph the period of a pendulum on the Mars with respect to its length in meters. For what length, in meters, will the period of a pendulum be three seconds?

17. The acceleration of gravity on the Earth depends on the latitude and altitude of a place. The value of \( g \) is slightly smaller for places closer to the Equator than places closer to the Poles, and the value of \( g \) is slightly smaller for places at higher altitudes that it is for places at lower altitudes. In Helsinki, the value of \( g = 9.819 \text{ m/s}^2 \), in Los Angeles the value of \( g = 9.796 \text{ m/s}^2 \) and in Mexico City the value of \( g = 9.779 \text{ m/s}^2 \). Graph the period of a pendulum with respect to its length for all three cities on the same graph. Use the formula to find the length (in meters) of a pendulum with a period of 8 seconds for each of these cities.
18. The aspect ratio of a wide screen TV is $2.39 : 1$. Graph the length of the diagonal of a screen as a function of the area of the screen. What is the diagonal of a screen with area 150 in$^2$?

In Exercises 19-22, graph the functions using a graphing calculator.

19. $f(x) = \sqrt{3x - 2}$
20. $f(x) = 4 + \sqrt{2 - x}$
21. $f(x) = \sqrt{x^2 - 9}$
22. $f(x) = \sqrt{x} - \sqrt{x + 2}$

Answers

1.

2.

3.

4.

5.

6.

7.
8. $L = 3.25$ feet.

9. $L = 4.05$ meters.

10. $L = 0.84$ meters.

11. Note: The differences are so small that all of the lines appear to coincide on this graph. If you zoom (way) in you can see slight differences.

The period of an 8 meter pendulum in Helsinki is 1.8099 seconds, in Los Angeles it is 1.8142 seconds, and in Mexico City it is 1.8173 seconds.

15.92 m Helsinki,

15.88 m Los Angeles,

15.85 m Mexico City.
18. \( D = 20.5 \) inches

19. Window \(-1 \leq x \leq 5; -5 \leq y \leq 5\)

20. Window \(-5 \leq x \leq 5; 0 \leq y \leq 10\)

21. Window \(-6 \leq x \leq 6; -1 \leq y \leq 10\)

22. Window \(0 \leq x \leq 5; -3 \leq y \leq 1\)
3.2 Radical Expressions I

In Exercises 1-4, without using a calculator, evaluate each radical expression.

1. $\sqrt{169}$
2. $\sqrt{81}$
3. $\sqrt[3]{-125}$
4. $\sqrt[4]{1024}$

In Exercises 5-8, write each expression as a rational exponent.

5. $3\sqrt[3]{14}$
6. $\sqrt[4]{zw}$
7. $\sqrt{a}$
8. $\sqrt[3]{y^3}$

In Exercises 9-16, write each expression in simplest radical form.

9. $\sqrt{24}$
10. $\sqrt{300}$
11. $\sqrt[3]{96}$
12. $\sqrt[3]{240}$
13. $\sqrt[4]{500}$
14. $\sqrt{64x^8}$
15. $\sqrt[3]{48a^3b^7}$
16. $\sqrt[3]{16x^5}$

In Exercises 17-22, simplify the expressions as much as possible.

17. $3\sqrt{8} - 6\sqrt{32}$
18. $\sqrt{180} + 6\sqrt{405}$
19. $\sqrt{6} - \sqrt{27} + 2\sqrt{27} + 3\sqrt{48}$
20. $\sqrt{8x^5} - 4x\sqrt{98x}$
21. $\sqrt{48a} + \sqrt{27a}$
22. $\sqrt[4]{4x^3} + x\sqrt{256}$

23. The volume of a spherical balloon is 950 cm$^3$. Find the radius of the balloon. (Volume of a sphere with radius $R$ is $V = \frac{4}{3}\pi R^3$).

Answers

1. 13
2. not a real solution
3. $-5$
4. 4
5. $14\frac{1}{2}$
6. $z\frac{3}{4}w\frac{1}{4}$
7. $a\frac{1}{2}$
8. $y\frac{1}{3}$
9. $2\sqrt{6}$
10. $10\sqrt{3}$
11. $2\sqrt{3}$
12. $\frac{4\sqrt{135}}{63}$
13. $5\sqrt{3}$
14. $2x\sqrt{x^2}$
15. $2ab^2\sqrt{3b}$
16. $\frac{2x\sqrt{5x^2y}}{15y^2}$
17. $-18\sqrt{2}$
18. $60\sqrt{5}$
19. $7\sqrt{6} + 9\sqrt{3}$
20. $-26x\sqrt{2x}$
21. $7\sqrt{3a}$
22. $5x\sqrt{4}$
23. $R = 6.1$ cm
### 3.3 Radical Expressions II

In Exercises 1-6, multiply and simplify the expressions.

1. \( \sqrt{6} \left( \sqrt{10} + \sqrt{8} \right) \)
2. \( \left( \sqrt{a} - \sqrt{b} \right) \left( \sqrt{a} + \sqrt{b} \right) \)
3. \( (2\sqrt{x} + 5) (2\sqrt{x} + 5) \)
4. \( \sqrt[4]{x} \)
5. \( \sqrt[7]{x} \)
6. \( \sqrt{x} \cdot \sqrt{x^2} \)
7. \( \sqrt{x^5} \cdot \sqrt{x} \)

In Exercises 7-15, simplify the quotients.

8. \( \frac{7}{\sqrt{15}} \)
9. \( \frac{9}{\sqrt{19}} \)
10. \( \frac{2x}{\sqrt{3x}} \)
11. \( \frac{\sqrt{5}}{\sqrt{3y}} \)
12. \( \frac{12}{2 - \sqrt{5}} \)
13. \( \frac{6 - \sqrt{3}}{4 - \sqrt{3}} \)
14. \( \frac{x}{\sqrt{2} + \sqrt{x}} \)
15. \( \frac{5y}{2\sqrt{y} - 5} \)

### Answers

1. \( 2\sqrt{15} + 4\sqrt{3} \)
2. \( a - b \)
3. \( 4x + 20\sqrt{x} + 25 \)
4. \( \frac{3\sqrt{x}}{2} \)
5. \( \frac{\sqrt{x}}{15} \)
6. \( \frac{\sqrt[3]{x^5}}{2} \)
7. \( \sqrt[6]{x^{17}} = x^2\sqrt{x^5} \)
8. \( \frac{7\sqrt{15}}{15} \)
9. \( \frac{9\sqrt{10}}{10} \)
10. \( \frac{2\sqrt{5}x}{5} \)
11. \( \frac{\sqrt{15y}}{3y} \)
12. \( -24 - 12\sqrt{5} \)
13. \( \frac{21 + 2\sqrt{3}}{7} \)
14. \( \frac{x\sqrt{2} - x\sqrt{x}}{2 - x} \)
15. \( \frac{10y\sqrt{y} + 25y}{4y - 25} \)
3.4 Radical Equations

In Exercises 1-16, find the solution to each radical equation. Identify extraneous solutions.

1. \( \sqrt{x + 2} - 2 = 0 \)
2. \( \sqrt{3x - 1} = 5 \)
3. \( 2\sqrt{4 - 3x} + 3 = 0 \)
4. \( 3\sqrt{x - 3} = 1 \)
5. \( \sqrt{x^2 - 9} = 2 \)
6. \( 3\sqrt{-2 - 5x} + 3 = 0 \)
7. \( \sqrt{x} = x - 6 \)
8. \( \sqrt{x^2 - 5x} - 6 = 0 \)
9. \( \sqrt{(x + 1)(x - 3)} = x \)
10. \( \sqrt{x + 6} = x + 4 \)
11. \( \sqrt{x} = \sqrt{x - 9} + 1 \)
12. \( \sqrt{3x + 4} = -6 \)
13. \( \sqrt{10 - 5x} + \sqrt{1 - x} = 7 \)
14. \( \sqrt{2x - 2} - 2\sqrt{x} + 2 = 0 \)
15. \( \sqrt{2x + 5} - 3\sqrt{2x - 3} = \sqrt{2 - x} \)
16. \( 3\sqrt{x} - 9 = \sqrt{2x - 14} \)

17. The area of a triangle is 24 in\(^2\) and the height of the triangle is twice as long as the base. What are the base and the height of the triangle?

18. The area of a circular disk is 124 in\(^2\). What is the circumference of the disk? (Area = \(\pi r^2\), Circumference = \(2\pi r\).)

19. The volume of a cylinder is 245 cm\(^3\) and the height of the cylinder is one third of the diameter of the base of the cylinder. The diameter of the cylinder is kept the same, but the height of the cylinder is increased by two centimeters. What is the volume of the new cylinder? (Volume = \(\pi r^2 h\).)

20. The height of a golf ball as it travels through the air is given by the equation \(h = -16t^2 + 256\). Find the time when the ball is at a height of 120 feet.

Answers

1. \( x = 2 \)
2. \( x = \frac{26}{3} \)
3. no real solution, extraneous solution \( x = \frac{7}{12} \)
4. \( x = 4 \)
5. \( x = 5 \) or \( x = -5 \)
6. \( x = 5 \)
7. \( x = 9 \), extraneous solution \( x = 4 \)
8. \( x = 9 \) or \( x = -4 \)
9. no real solution, extraneous solution \( x = -\frac{3}{2} \)
10. \( x = -2 \), extraneous solution \( x = -5 \)
11. \( x = 25 \)
12. no real solution, extraneous solution \( x = \frac{32}{3} \)
13. \( x = -3 \), extraneous solution \( x = -\frac{117}{4} \)
14. \( x = 9, x = 1 \)
15. \( x = 2, x = \frac{62}{33} \)
16. \( x = 25 \), extraneous solution \( x = \frac{361}{49} \)
17. base = 4.9 in, height = 9.8 in
18. circumference = 39.46 in
19. volume = 394.94 cm\(^3\)
20. time = 2.9 seconds
3.5 Imaginary and Complex Numbers

In Exercises 1-6, simplify the radicals.

1. \(\sqrt{-9}\)
2. \(\sqrt{-12}\)
3. \(\sqrt{140 - 108}\)
4. \(\sqrt{-17}\)
5. \(\frac{15 - 5\sqrt{-11}}{5}\)
6. \(\frac{6 + \sqrt{-24}}{4}\)

Answers

1. \(3i\)
2. \(2i\sqrt{3}\)
3. \(4\sqrt{2}\)
4. \(i\sqrt{17}\)
5. \(3 - i\sqrt{11}\)
6. \(\frac{3 + i\sqrt{6}}{2}\)
Chapter 4

Quadratic Functions

4.1 Graphs of Quadratic Functions

Find the vertex and intercepts of the following quadratics. Use this information to graph the quadratic.

1. \( y = x^2 - 2x - 8 \)
2. \( y = x^2 - 2x - 3 \)
3. \( y = 2x^2 - 12x + 10 \)
4. \( y = 2x^2 - 12x + 16 \)
5. \( y = -2x^2 + 12x - 18 \)
6. \( y = -2x^2 + 12x - 10 \)
7. \( y = -3x^2 + 24x - 45 \)
8. \( y = -3x^2 + 12x - 9 \)
9. \( y = -x^2 + 4x + 5 \)
10. \( y = -x^2 + 4x - 3 \)
11. \( y = -x^2 + 6x - 5 \)
12. \( y = -2x^2 + 16x - 30 \)
13. \( y = -2x^2 + 16x - 24 \)
14. \( y = 2x^2 + 4x - 6 \)
15. \( y = 3x^2 + 12x + 9 \)
16. \( y = 5x^2 + 30x + 45 \)
17. \( y = 5x^2 - 40x + 75 \)
18. \( y = 5x^2 + 20x + 15 \)
19. \( y = -5x^2 - 60x - 175 \)
20. \( y = -5x^2 + 20x - 15 \)

Answers

1.

16. \((0, 45)\) \((-3, 0)\)
4.2 Solving Quadratic Equations by Graphing

In Exercises 1-6, find the solutions of the equations by graphing.

1. \( x^2 + 3x + 6 = 0 \) 
2. \( -2x^2 + x + 4 = 0 \) 
3. \( x^2 - 9 = 0 \) 
4. \( x^2 + 6x + 9 = 0 \) 
5. \( 10x - 3x^2 = 0 \) 
6. \( \frac{1}{2}x^2 - 2x + 3 = 0 \)

In Exercises 7-12, find the roots of the quadratic equations by graphing.

7. \( y = -3x^2 + 4x - 1 \) 
8. \( y = 9 - 4x^2 \) 
9. \( y = x^2 + 7x + 2 \) 
10. \( y = -x^2 - 10x - 25 \) 
11. \( y = 2x^2 - 3x \) 
12. \( y = x^2 - 2x + 5 \)

In Exercises 13-15, using your graphing calculator.

(a) Find the roots of the quadratic polynomials.
(b) Find the vertex of the quadratic polynomials.

13. \( y = x^2 + 12x + 5 \) 
14. \( y = x^2 + 3x + 6 \) 
15. \( y = -x^2 - 3x + 9 \)

16. Use your graphing calculator to solve Ex. # 5. You should get the same answers as we did graphing by hand but a lot quicker!

17. Peter throws a ball and it takes a parabolic path. Here is the equation of the height of the ball with respect to time: \( y = -16t^2 + 60t \), where \( y \) represents the height in feet and \( t \) represents the time in seconds. Find how long it takes the ball to come back to the ground.

Answers

1. no real solutions 
2. \( x \approx -1.2, x \approx 1.7 \)
3. \( x = -3, x = 3 \)

4. \( x = -3 \) (double root)

5. \( X = 0, x \approx 3.33 \)

6. no real solutions

7. \( x \approx 0.33, x = 1 \)

8. \( x = -1.5, x = 1.5 \)
9. \( x = -6.67, x = -0.33 \)

10. \( x = -5 \) (double root)

11. \( x = 0, x = 1.5 \)

12. no real solutions

13. \( x \approx -11.6 \) and \( x \approx -0.4 \). Vertex \((-6, -31)\)

17. time = 3.75 seconds.

14. no real solutions. Vertex \((-3/2, 15/4)\)

15. (a) \( x \approx -4.9 \) and \( x \approx 1.9 \)
   (b) Vertex: \((-1.5, 11.25)\)

16. \( x \approx 9.8 \) seconds
4.3 Solving Quadratic Equations by Square Roots

In Exercises 1-28, solve the quadratic equations by hand.

1. $x^2 - 1 = 0$
2. $x^2 - 100 = 0$
3. $x^2 + 16 = 0$
4. $9x^2 - 1 = 0$
5. $4x^2 - 49 = 0$
6. $64x^2 - 9 = 0$
7. $x^2 - 81 = 0$
8. $25x^2 - 36 = 0$
9. $x^2 + 9 = 0$
10. $x^2 - 16 = 0$
11. $x^2 - 36 = 0$
12. $16x^2 - 49 = 0$
13. $(x - 2)^2 = 1$
14. $(x + 5)^2 = 16$
15. $(2x - 1)^2 - 4 = 0$
16. $(3x + 4)^2 = 9$
17. $(x - 3)^2 + 25 = 0$
18. $x^2 - 6 = 0$
19. $x^2 - 20 = 0$
20. $3x^2 + 14 = 0$
21. $(x - 6)^2 = 5$
22. $(4x + 1)^2 - 8 = 0$
23. $x^2 - 10x + 25 = 9$
24. $x^2 + 18x + 81 = 1$
25. $4x^2 - 12x + 9 = 16$
26. $(x + 10)^2 = 2$
27. $x^2 + 14x + 49 = 3$
28. $2(x + 3)^2 = 8$

29. Susan drops her camera in the river from a bridge that is 400 feet high. How long is it before she hears the splash?

30. It takes a rock 5.3 seconds to splash in the water when it is dropped from the top of a cliff. How high is the cliff in meters?

Answers

1. $x = 1$, $x = -1$
2. $x = 10$, $x = -10$
3. no real solution.
4. $x = \frac{1}{3}$, $x = -\frac{1}{3}$
5. $x = \frac{7}{2}$, $x = -\frac{7}{2}$
6. $x = \frac{3}{8}$, $x = -\frac{3}{8}$
7. $x = 9$, $x = -9$
8. $x = \frac{6}{5}$, $x = -\frac{6}{5}$
9. no real solution.
10. $x = 4$, $x = -4$
11. $x = 6$, $x = -6$
12. $x = \frac{7}{4}$, $x = -\frac{7}{4}$
13. $x = 3$, $x = 1$
14. $x = -1$, $x = -9$
15. $x = \frac{3}{2}$, $x = -\frac{1}{2}$
16. $x = -\frac{1}{3}$, $x = -\frac{7}{3}$
17. no real solution.
18. $x \approx 2.45$, $x \approx -2.45$
19. $x \approx 4.47$, $x \approx -4.47$
20. no real solution.
21. $x \approx 8.24$, $x \approx 3.76$
22. $x \approx 0.46$, $x \approx -0.96$
23. $x = 8$, $x = 2$
24. $x = -8$, $x = -10$
25. $x = \frac{7}{2}$, $x = -\frac{1}{2}$
26. $x \approx -8.59$, $x \approx -11.41$
27. $x \approx -5.27$, $x \approx -8.73$
28. $x = -1$, $x = -5$
29. $t = 5$ seconds
30. $y_o = 137.6$ meters.
4.4  Solving Quadratic Equations using the Quadratic Formula

In Exercises 1-8, solve the quadratic equations using the quadratic formula.

1. \(x^2 + 4x - 21 = 0\)  
2. \(x^2 - 6x = 12\)  
3. \(3x^2 - \frac{1}{2}x = \frac{3}{8}\)  
4. \(2x^2 + x - 3 = 0\)  
5. \(-x^2 - 7x + 12 = 0\)  
6. \(-3x^2 + 5x = 0\)  
7. \(4x^2 = 0\)  
8. \(x^2 + 2x + 6 = 0\)

In Exercises 9-20, solve the quadratic equations using the method of your choice.

9. \(x^2 - x = 6\)  
10. \(x^2 - 12 = 0\)  
11. \(-2x^2 + 5x - 3 = 0\)  
12. \(x^2 + 7x - 18 = 0\)  
13. \(3x^2 + 6x = -10\)  
14. \(-4x^2 + 4000x = 0\)  
15. \(-3x^2 + 12x + 1 = 0\)  
16. \(x^2 + 6x + 9 = 0\)  
17. \(81x^2 + 1 = 0\)  
18. \(-4x^2 + 4x = 9\)  
19. \(36x^2 - 21 = 0\)  
20. \(x^2 - 2x - 3 = 0\)

21. The product of two consecutive integers is 72. Find the two numbers.

22. The product of two consecutive odd integers is 1 less than 3 times their sum. Find the integers.

23. The length of a rectangle exceeds its width by 3 inches. The area of the rectangle is 70 square inches, find its dimensions.

24. Angel wants to cut off a square piece from the corner of a rectangular piece of plywood. The larger piece of wood is 4 feet \(\times\) 8 feet and the cutoff part is \(\frac{1}{5}\) of the total area of the plywood sheet. What is the length of the side of the square?

![Diagram of a house and a patio]

25. Mike wants to fence three sides of a rectangular patio that is adjacent the back of his house. The area of the patio is 192 ft\(^2\) and the length is 4 feet longer than the width. Find how much fencing Mike will need.

26. An object is moving in a straight line. It initially travels at a speed of 9 meters per second, and it speeds up at a constant rate of 2 meters per second each sec on. Under such conditions, the distance \(d\), in meters, that the object travels is given by the equation \(d = t^2 + 9t\), where \(t\) is in seconds. According to this equation, how long will it take the object to travel 22 meters.

27. The profit \(P\), in dollars, gained by selling \(x\) computers is modeled by the equation \(P = -5x^2 + 1000x + 5000\). How many computers must be sold to obtain a profit of $55,000.
28. The entrance to an athletic field is in the shape of a parabolic archway. The archway is modeled by the equation \( d = 12x - x^2 \), where \( d \) represents the distance, in feet, that the arch is above the ground for any \( x \) value.

(a) For what values of \( x \) will the arch be 20 feet above the ground?
(b) How many feet wide is the base of the arch?
(c) What is the maximum height of the arch above the ground?

29. As illustrated below, a frame for a picture is \( 2\frac{1}{2} \) inches wide. The picture enclosed by the frame is 5 inches longer than it is wide. If the area of the picture itself is 300 square inches, determine the outer dimensions of the frame.

![Diagram of a picture frame](image)

**Answers**

1. \( x = -7, \ x = 3 \)
2. \( x = 3 \pm \sqrt{21} \)
3. \( x = \frac{1}{12} \pm \frac{\sqrt{19}}{12} \)
4. \( x = -\frac{3}{2}, \ x = 1 \)
5. \( x = -\frac{7}{2} \pm \frac{\sqrt{97}}{2} \)
6. \( x = 0, \ x = \frac{5}{3} \)
7. \( x = 0 \)
8. \( -1 \pm i\sqrt{5} \)
9. \( x = -2, \ x = 3 \)
10. \( x = \pm 2\sqrt{3} \)
11. \( x = 1, \ x = \frac{3}{2} \)
12. \( x = -9, \ x = 2 \)
13. \( x = -1 \pm \frac{i\sqrt{21}}{3} \)
14. \( x = 0, \ x = 1000 \)
15. \( x = 2 \pm \frac{\sqrt{39}}{3} \)
16. \( x = -3 \)
17. \( x = \pm \frac{1}{9}i \)
18. \( \frac{1}{2} \pm i\sqrt{2} \)
19. \( x = \pm \frac{\sqrt{21}}{6} \)
20. \( x = -1, \ x = 3 \)
21. 8 and 9
22. 5 and 7
23. 7 in and 10 in
24. side = 3.27 ft
25. 40 feet of fencing
26. 2 seconds
27. 100 computers
28. (a) 2 ft to 10 ft, (b) 12 ft, (c) 36 in.
29. width: 20 in, length: 25 in
4.5 The Discriminant

In Exercises 1-6, find the discriminant of each quadratic equation.

1. \(2x^2 - 4x + 5 = 0\)  
2. \(x^2 - 5x = 8\)  
3. \(4x^2 - 12x + 9 = 0\)  
4. \(x^2 + 3x + 2 = 0\)  
5. \(x^2 - 16x = 32\)  
6. \(-5x^2 + 5x - 6 = 0\)

In Exercises 7-12, determine the nature of the solutions of each quadratic equation (none, unique solution, two solutions, real, imaginary...)

7. \(-x^2 + 3x - 6 = 0\)  
8. \(5x^2 = 6x\)  
9. \(41x^2 - 31x - 52 = 0\)  
10. \(x^2 - 8x + 16 = 0\)  
11. \(-x^2 + 3x - 10 = 0\)  
12. \(x^2 - 64 = 0\)

In Exercises 13-18, without solving the equation, determine whether the solutions will be rational or irrational.

13. \(x^2 = -4x + 20\)  
14. \(x^2 + 2x - 3 = 0\)  
15. \(3x^2 - 11x = 10\)  
16. \(\frac{1}{2}x^2 + 2x + \frac{2}{3} = 0\)  
17. \(x^2 - 10x + 25 = 0\)  
18. \(x^2 = 5x\)

19. Marty is outside his apartment building. He needs to give Yolanda her cell phone but he does not have time to run upstairs to the third floor to give it to her. He throws it straight up with a vertical velocity of 55 feet/second. Will the phone reach her if she is 36 feet up? (Hint: The equation for the height is given by \(y = -32t^2 + 55t + 4\).)

20. Bryson owns a business that manufactures and sells tires. The revenue from selling the tires in the month of July is given by the function \(R = x(200 - 0.4x)\) where \(x\) is the number of tires sold. Can Bryson's business generate revenue of $20,000 in the month of July?

Answers

1. \(D = -24\)  
2. \(D = 57\)  
3. \(D = 0\)  
4. \(D = 1\)  
5. \(D = 384\)  
6. \(D = -95\)  
7. \(D = -15\)  
8. \(D = 36\)  
9. \(D = 9489\)  
10. \(D = 0\)

11. \(D = -31\) no real solutions  
12. \(D = 256\) two real solutions  
13. \(D = 96\) two real irrational solutions  
14. \(D = 16\) two real rational solutions  
15. \(D = 241\) two real irrational solutions  
16. \(D = \frac{8}{3}\) two real irrational solutions  
17. \(D = 0\) one real rational solution  
18. \(D = 25\) two real rational solutions  
19. no  
20. yes
Chapter 5

Exponential Functions

5.1 Exponents Properties Involving Products

In Exercises 1-4, write in exponential notation.

1. \(4 \cdot 4 \cdot 4 \cdot 4 \cdot 4\)
2. \(3x \cdot 3x \cdot 3x\)
3. \((-2a) \cdot (-2a) \cdot (-2a) \cdot (-2a)\)
4. \(6 \cdot 6 \cdot 6 \cdot x \cdot y \cdot y \cdot y \cdot y\)

In Exercises 5-8, find each number.

5. \(5^4\)
6. \((-2)^6\)
7. \((0.1)^5\)
8. \((-0.6)^3\)

In Exercises 9-14, multiply and simplify.

9. \(6^3 \cdot 6^6\)
10. \(2^2 \cdot 2^4 \cdot 2^6\)
11. \(3^2 \cdot 4^3\)
12. \(x^2 \cdot x^4\)
13. \((-2y^4)(-3y)\)
14. \((4a^2)(-3a)(-5a^4)\)

In Exercises 15-22, simplify.

15. \((a^3)^4\)
16. \((xy)^2\)
17. \((3a^2b^3)^4\)
18. \((-2xy^4z^2)^5\)
19. \((-8x)^3 (5x)^2\)
20. \((4a^2) (-2a^3)^4\)
21. \((12xy)(12xy)^2\)
22. \((12xy^2) (-x^2 y)^2 (3x^2 y^2)\)

Answers

1. \(4^5\)
2. \((3x)^3\)
3. \((-2a)^4\)
4. \(6^3 x^2 y^4\)
5. \(625\)
6. \(64\)
7. \(0.00001\)
8. \(-0.216\)
9. \(10077696\)
10. \(4096\)
11. \(576\)
12. \(x^6\)
13. \(6y^5\)
14. \(60a^7\)
15. \(a^{12}\)
16. \(x^2 y^2\)
17. \(81a^8 b^{12}\)
18. \(-32x^5 y^{20} z^{10}\)
19. \(-12800x^5\)
20. \(64x^{14}\)
21. \(1728x^3 y^3\)
22. \(36x^7 y^6\)
5.2 Exponent Properties Involving Quotients

In Exercises 1-4, evaluate the expressions.

1. \( \frac{5^6}{3^2} \)  \hspace{1cm} 2. \( \frac{6^7}{6^3} \)  \hspace{1cm} 3. \( \frac{3^4}{3^{10}} \)  \hspace{1cm} 4. \( \left( \frac{2^2}{3^3} \right)^3 \)

In Exercises 5-16, evaluate the expressions.

5. \( \frac{a^3}{a^2} \)  \hspace{1cm} 6. \( \frac{x^5}{x^9} \)  \hspace{1cm} 7. \( \left( \frac{a^3b^4}{a^2b} \right)^3 \)  \hspace{1cm} 8. \( \frac{x^6y^2}{x^2y^5} \)

9. \( \frac{6a^3}{2a^2} \)  \hspace{1cm} 10. \( \frac{15x^5}{5x} \)  \hspace{1cm} 11. \( \left( \frac{18a^4}{15a^{10}} \right)^{14} \)  \hspace{1cm} 12. \( \frac{25yx^6}{20y^5x^2} \)

13. \( \left( \frac{x^6y^2}{x^4y^7} \right)^3 \)  \hspace{1cm} 14. \( \left( \frac{6a^2}{4b^4} \right)^2 \cdot \frac{5b}{3a} \)  \hspace{1cm} 15. \( \frac{(3ab)^2 (4a^3b^4)^3}{(6a^2b^4)^3} \)

16. \( \frac{(2a^2bc^2)(6abc^3)}{4ab^2c} \)

Answers

1. \( 5^4 \)  \hspace{1cm} 6. \( \frac{1}{x^3} \)  \hspace{1cm} 10. \( 3x^4 \)  \hspace{1cm} 14. \( \frac{15a^3}{4b^7} \)

2. \( 6^4 = 1296 \)  \hspace{1cm} 7. \( a^3b^9 \)  \hspace{1cm} 11. \( \frac{1296}{625a^4} \)  \hspace{1cm} 15. \( \frac{4a^3b^{10}}{9} \)

3. \( \frac{1}{3^6} = \frac{1}{729} \)  \hspace{1cm} 8. \( \frac{x^4}{y^5} \)  \hspace{1cm} 12. \( \frac{5x^4}{4y^4} \)  

4. \( \frac{2^6}{3^9} = \frac{64}{19683} \)  \hspace{1cm} 9. \( 3a \)  \hspace{1cm} 13. \( \frac{x^6}{y^6} \)  \hspace{1cm} 16. \( 3a^2c^4 \)
5.3 **Zero, Negative, and Fractional Exponents**

In Exercises 1-8, simplify the expressions. Be sure that there aren’t any negative exponents in the answer.

1. \(x^{-1} \cdot y^2\)
2. \(x^{-4}\)
3. \(\frac{x^{-3}}{x^{-7}}\)
4. \(\frac{x^{-3}y^{-5}}{z^{-7}}\)
5. \((x^{1/2}y^{-2/3}) (x^2y^{1/3})\)
6. \((\frac{a}{b})^{-2}\)
7. \((3a^{-2}b^2c^3)^3\)
8. \(x^{-3} \cdot x^3\)

In Exercises 9-16, simplify the expressions so that there aren’t any fractions in the answer.

9. \(\frac{a^{-3}(a^5)}{a^{-6}}\)
10. \(\frac{5x^6y^2}{x^8y}\)
11. \(\frac{(4ab^6)^3}{(ab)^5}\)
12. \(\left(\frac{3x}{y^{1/3}}\right)^3\)
13. \(\frac{3x^2y^{3/2}}{xy^{1/2}}\)
14. \(\frac{(3x^3)(4x^4)}{(2y)^2}\)
15. \(\frac{a^{-2}b^{-3}}{c^{-1}}\)
16. \(\frac{x^{1/2}y^{5/2}}{x^{3/2}y^{3/2}}\)

In Exercises 17-24, evaluate the expressions to a single number.

17. \(3^{-2}\)
18. \((6.2)^0\)
19. \(8^{-4} \cdot 8^6\)
20. \((16^{1/2})^3\)
21. \(x^24x^3y^4y^2\) if \(x = 2\) and \(y = -1\)
22. \(a^4(b^3)^3 + 2ab\) if \(a = -2\) and \(b = 1\)
23. \(5x^2 - 2y^3 + 3z\) if \(x = 3, y = 2,\) and \(z = 4\)
24. \(\left(\frac{a^2}{b^4}\right)^{-2}\) if \(a = 5\) and \(b = 3\)

**Answers**

1. \(\frac{y^2}{x}\)
2. \(\frac{1}{x^4}\)
3. \(x^4\)
4. \(\frac{x^7}{x^3y^5}\)
5. \(\frac{x^{5/2}}{y^{1/3}}\)
6. \(\left(\frac{b}{a}\right)^2\) or \(\frac{b^2}{a^2}\)
7. \(\frac{27b^6c^9}{a^6}\)
8. 1
9. \(a^8\)
10. \(5x^{-2}y\)
11. \(64a^{-2}b^{1/3}\)
12. \(27x^2y^{-1}\)
13. \(3xy\)
14. \(6x^7y^{-2}\)
15. \(a^{-2}b^{-3}c\)
16. \(x^{-1}y\)
17. 0.111
18. 1
19. 64
20. 64
21. 512
22. 12
23. 41
24. 1.1664
### 5.4 Scientific Notation

1. Write the numerical value of the following.
   
   \( (a) \ 3.102 \times 10^2 \quad (b) \ 7.4 \times 10^4 \quad (c) \ 1.75 \times 10^{-3} \quad (d) \ 2.9 \times 10^{-5} \quad (e) \ 9.99 \times 10^{-9} \)

2. Write the following numbers in scientific notation.
   
   \( (a) \ 120,000 \quad (b) \ 1,765,244 \quad (c) \ 12 \quad (d) \ 0.00281 \quad (e) \ 0.000000027 \)

3. The moon is approximately a sphere with radius \( r = 1.08 \times 10^3 \) miles. Use the formula \( \text{Surface Area} = 4\pi r^2 \) to determine the surface area of the moon, in square miles. Express your answer in scientific notation, rounded to 2 significant figures.

4. The charge on one electron is approximately \( 1.60 \times 10^{-19} \) coulombs. One Faraday is equal to the total charge on \( 6.02 \times 10^{23} \) electrons. What, in coulombs, is the charge on one Faraday?

5. Proxima Centauri, the next closest star to our Sun is approximately \( 2.5 \times 10^{13} \) miles away. If light from Proxima Centauri takes \( 3.7 \times 10^4 \) hours to reach us from there, calculate the speed of light in miles per hour. Express your answer in scientific notation, rounded to 2 significant figures.

**Answers**

1. \( (a) \ 310.2 \quad (b) \ 74.000 \quad (c) \ 0.00175 \quad (d) \ 0.000029 \quad (e) \ 0.0000000999 \)

2. \( (a) \ 1.2 \times 10^5 \quad (b) \ 1.765224 \times 10^{10} \quad (c) \ 1.2 \times 10^1 \quad (d) \ 2.81 \times 10^{-3} \quad (e) \ 2.7 \times 10^{-8} \)

3. \( 1.5 \times 10^7 \) miles\(^2\)

4. 96,320 or \( 9.632 \times 10^4 \)

5. \( 6.8 \times 10^8 \) miles per hour.
### 5.5 Exponential Functions

1. For the function \( f(x) = 2^{3x-1} \), find \( f(0) \), \( f(2) \), and \( f(-2) \).

2. Graph the functions \( f(x) = 3^x \) and \( g(x) = 3^{x+5} - 1 \). State the domain and range of each function.

3. Graph the functions \( a(x) = 4^x \) and \( b(x) = 4^{-x} \). State the domain and range of each function.

4. Graph the function \( h(x) = -2^{x-1} \) using transformations. How is the graph of \( h(x) \) related to \( y = 2^x \)?

5. Solve the equation: \( 5^{2x+1} = 25^{3x} \).

6. Solve the equation: \( 4^{x^2+1} = 16^x \).

7. Use a graph to find an approximate solution to the equation \( 3^x = 14 \).

8. Use a graph to find an approximate solution to the equation \( 2^{-x} = 7^{2x+9} \).

9. Sketch a graph of the function \( f(x) = 3^x \) and its inverse. (Hint: You can graph the inverse by reflecting a function across the line \( y = x \).) Is \( f \) one-to-one?

10. Consider the following situation: you inherited a collection of 125 stamps from a relative. You decided to continue to build the collection, and you vowed to double the size of the collection every year.

   (a) Write an exponential function to model the situation. (The input of the function is the number of years since you began building the collection, and the output is the size of the collection.)

   (b) Use your model to determine how long it will take to have a collection of 10,000 stamps.

### Answers

1. \( f(0) = 1/2 \), \( f(2) = 32 \), \( f(-2) = 1/128 \).

2. The domain of both functions is the set of all real numbers. The range of \( f \) is the set of all real numbers greater than or equal to 0. The range of \( g \) is the set of all real numbers greater than or equal to \(-1\).

3. The domain of both functions is the set of all real numbers. The range of both functions is the set of all real numbers greater than or equal to 0.

3. \[ g(x) = 3^{x+1} - 1 \]

4. If we start with the function \( y = 2^x \), the graph of \( h(x) \) represents a reflection over the \( y \)-axis,
and a horizontal shift 1 unit to the right.

\[ 5^{2x+1} = 25^{2x} \]
\[ 5^{2x+1} = 5^{6x} \]
\[ 2x + 1 = 6x \]
\[ 4x = 1 \]
\[ x = \frac{1}{4} \]

5.

\[ 4^{x^2+1} = 16^x \]
\[ 4^{x^2+1} = 4^{2x} \]
\[ x^2 + 1 = 2x \]
\[ x^2 - 2x + 1 = 0 \]
\[ (x - 1)(x - 1) = 0 \]
\[ x = 1 \]

6.

7. \( x \approx 2.4 \)

8. \( x \approx -3.8 \)

9. \( f \) is a one-to-one function.

10. (a) \( S(t) = 125(2)^t \). (b) About 6.2 years
5.6 Finding Equations of Exponential Functions

1. Some values of functions, \( f, g, h, \) and \( k \) are provided in the table. Determine if each function is linear or exponential and find equations for each.

<table>
<thead>
<tr>

In Exercises 2-15, find an equation of the form \( y = ab^x \), of the exponential curve that contains the given pair of points. Round the values of \( a \) and \( b \) to 2 decimal places if necessary.

2. \((0, 4)\) and \((1, 12)\)  
3. \((0, 7)\) and \((1, 35)\)  
4. \((0, 1)\) and \((1, 6)\)  
5. \((0, 2)\) and \((1, 14)\)  
6. \((1, 18)\) and \((2, 108)\)  
7. \((1, 45)\) and \((2, 405)\)  
8. \((1, 70)\) and \((2, 700)\)

<table>
<thead>
<tr>
<th>( x )</th>
<th>( f(x) )</th>
<th>( g(x) )</th>
<th>( h(x) )</th>
<th>( k(x) )</th>
</tr>
</thead>
</table>
| 2. \( y = 4(3)^x \) | 9. \( y = 2(8)^x \)  
3. \( y = 7(5)^x \) | 10. \( y = 2(4)^x \)  
4. \( y = 6^x \) | 11. \( y = 11(2)^x \)  
5. \( y = 2(7)^x \) | 12. \( y = 8(3)^x \)  
6. \( y = 3(6)^x \) | 13. \( y = 3(7)^x \)  
7. \( y = 5(9)^x \) | 14. \( y = 3(0.88)^x \)  
8. \( y = 7(10)^x \) | 15. \( y = 0.11(2.06)^x \)  

Answers

1. \( f(x) \) is exponential since the common ratio is \( \frac{1}{2} \), \( f(x) = 80 \left( \frac{1}{2} \right)^x \)  
\( g(x) \) is linear since the common difference is \(-40\), \( g(x) = -40x + 80 \)  
\( h(x) \) is linear since the common difference is \( 10 \), \( h(x) = 10x + 5 \)  
\( k(x) \) is exponential since the common ratio is \( 3 \), \( k(x) = 5(3)^x \)
5.7 Composite Functions and Inverse Functions

1. Find the inverse of the function \( f(x) = \frac{1}{2}x - 7 \)

2. Use the horizontal line test to determine if the function \( f(x) = x + \frac{1}{x} \) is invertible or not.

3. Use composition of functions to determine if the functions are inverses: \( g(x) = 2x - 6 \) and \( h(x) = \frac{1}{2}x + 3 \)

4. Use composition of functions to determine if the functions are inverses \( f(x) = x + 2 \) and \( p(x) = x - \frac{1}{2} \)

5. Given the function \( f(x) = (x + 1)^2 \), how should the domain be restricted so that the function is invertible?

6. Consider the function \( f(x) = \frac{3}{2}x + 4 \)
   (a) Find the inverse of the function.
   (b) State the slope of the function and its inverse. What do you notice?

7. Given the function \( \{(0, 5), (1, 7), (2, 13), (3, 19)\} \)
   (a) Find the inverse of the function.
   (b) State the domain and range of the function.
   (c) State the domain and range of the inverse.

8. Consider the function \( a(x) = |x| \)
   (a) Graph the inverse.
   (b) Based on the graph, is the function invertible? Explain.

9. Consider the function \( f(x) = c \), where \( c \) is a real number. What is the inverse? Is \( f \) invertible? Explain.

10. A store sells fabric by the length. Red velvet goes on sale after Valentine’s Day for $4.00 per foot.
    (a) Write a function to model the cost of \( x \) feet of red velvet.
    (b) What is the inverse of this function?
    (c) What does the inverse represent?

Answers

1. \( f^{-1}(x) = 2x + 14 \)
   2. The function is not invertible.

3. The functions are inverses.
   \[
   g(h(x)) = g\left(\frac{1}{2}x + 3\right) = 2\left(\frac{1}{2}x + 3\right) - 6 = x + 6 - 6 = x \\
   h(g(x)) = h(2x - 6) = \frac{1}{2}(2x - 6) + 3 = x - 3 + 3 = x
   \]

4. The functions are not inverses.
   \[
   f(p(x)) = (x - \frac{1}{2}) + 2 = x + \frac{3}{2} \neq x
   \]

5. The domain should be restricted so that \( x \geq -1 \)

6. (a) \( y = \frac{2}{3}x - \frac{8}{3} \)
   (b) The slope of the function is \( \frac{2}{3} \) and the slope of the inverse is \( \frac{3}{2} \). The slopes are reciprocals.

7. (a) \( \{(5, 0), (7, 1), (13, 2), (19, 3)\} \)
   (b) Domain: \( \{0, 1, 2, 3\} \) and Range: \( \{5, 7, 13, 19\} \)
   (c) Domain: \( \{5, 7, 13, 19\} \) and Range: \( \{0, 1, 2, 3\} \)
8. (a)

(b) The function is not invertible. The inverse fails the vertical line test (the original function fails the horizontal line test).

9. The function $f$ is a horizontal line with equation $y = c$. The domain is the set of all real numbers, and the range is the single value $c$. Therefore the inverse would be a function whose domain is $c$ and the range is all real numbers. This is the vertical line $x = c$. This is not a function. So $f(x) = c$ is not invertible.

10. (a) $C(x) = 4x$
(b) $C^{-1}(x) = \frac{1}{4}x$
(c) The inverse function tells you the number of feet you bought, given the amount of money spent.
Chapter 6

Logarithmic Functions

6.1 Logarithmic Functions

In Exercises 1-2, write the exponential statement in logarithmic form.

1. \(3^2 = 9\) 
2. \(z^4 = 10\)

In Exercises 3-4, write the logarithmic statement in exponential form.

3. \(\log_5 25 = 2\) 
4. \(\log_4 \frac{1}{4} = -1\)

5. Complete the table of values for the function \(f(x) = \log_3 x\).

<table>
<thead>
<tr>
<th>(x)</th>
<th>(\frac{1}{9})</th>
<th>(\frac{1}{3})</th>
<th>1</th>
<th>3</th>
<th>9</th>
</tr>
</thead>
<tbody>
<tr>
<td>(y = f(x))</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

6. Use the table above to graph \(f(x) = \log_3 x\). State the domain and range of the function.

7. Consider \(g(x) = -\log_3(x - 2)\)

   (a) How is the graph of \(g(x)\) related to the graph of \(f(x) = \log_3 x\)?

   (b) Graph \(g(x)\) by transforming the graph of \(f(x)\).

8. Solve each logarithmic equation:

   (a) \(\log_3(9x) = 4\) 

   (b) \(7 + \log_2 x = 11\)

9. Solve each logarithmic equation:

   (a) \(\log_5(6x) = -1\) 

   (c) \(\log_5(6x) = \log_5(3x - 10)\)

   (b) \(\log_5(6x) = \log_5(2x + 16)\)

10. Explain why the equation in #9c has no solution?
Answers

1. \( \log_3(9) = 2 \)
2. \( \log_x(10) = 4 \)
3. \( 5^2 = 25 \)
4. \( 6^{-1} = \frac{1}{6} \)

<table>
<thead>
<tr>
<th>( x )</th>
<th>( \frac{1}{5} )</th>
<th>( \frac{1}{3} )</th>
<th>1</th>
<th>3</th>
<th>9</th>
</tr>
</thead>
<tbody>
<tr>
<td>( y = f(x) )</td>
<td>-2</td>
<td>-1</td>
<td>0</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

5. D: All real numbers > 0
R: All real numbers.

6. (a) The graph of \( g(x) \) can be obtained by shifting the graph of \( f(x) \) two units to the right, and reflecting it over the \( x \)-axis.

7. (a) \( x = 9 \)
(b) \( x = 16 \)

8. (a) \( x = 1/30 \)
(b) \( x = 4 \)
(c) no solution

9. (a) \( x = 9 \)
(b) \( x = 16 \)

10. When we solve \( 6x = 3x - 10 \) we find that \( x = -10/3 \), a value outside of the domain. Because there is no other \( x \) value that satisfies the equation, there is no solution.
6.2 Properties of Logarithms

In Exercises 1-2, expand the expression

1. \( \log_b(5x^2) \).
2. \( \log_3(81x^5) \).

In Exercises 3-4, condense the expression using properties of logarithms to rewrite as a single logarithm:

3. \( \log(x + 1) + \log(x - 1) \)
4. \( 3 \ln(x) + 2 \ln(y) - \ln(5x - 2) \)

In Exercises 4-6, evaluate the expressions:

5. (a) \( \log 1000 \) (b) \( \log 0.01 \)
6. (a) \( \ln e^4 \) (b) \( \ln \left( \frac{1}{e^y} \right) \)

7. Use the change of base formula to find the value of \( \log_5 100 \).

8. What is the difference between \( \log_b x^n \) and \( (\log_b x)^n \)?

9. Condense and rewrite the expression as a single logarithm to simplify: \( 3 \log 2 + \log 125 \)

10. Is this equation true for any values of \( x \) and \( y \)? \( \log_2(x + y) = \log_2 x + \log_2 y \). If so, give the values. If not, explain why not.

Answers

1. \( \log_b 5 + 2 \log_b x \)
2. \( 4 + 5 \log_3 x \)
3. \( \log(x^2 - 1) \)
4. \( \ln \left( \frac{x^3y^2}{5x - 2} \right) \)
5. (a) 3 (b) -2
6. (a) 4 (b) -9
7. \( \frac{\log 100}{\log 5} \approx 2.86 \)
8. The first expression is equivalent to \( n \log_b x \).
   The second expression is the \( n^{th} \) power of the log.
9. \( \log 1000 = 3 \)
10. Since \( \log_2(xy) = \log_2 x + \log_2 y \), \( \log_2(x + y) = \log_2 x + \log_2 y \) if and only if \( x + y = xy \). The solution to this equation are all positive values of \( x \) and \( y \) for which \( x + y = xy \). For example, \( x = 3 \) and \( y = 1.5 \).
6.3 Exponential and Logarithmic Models and Equations

For question 1-5, solve each equation using algebraic methods. Given an exact solution.

1. \(2(5^{x-4}) + 7 = 43\)
2. \(4^x = 7^{3x-5}\)
3. \(\log(5x + 200) + \log 2 = 3\)
4. \(\log_3(4x + 5) - \log_3 x = 2\)
5. \(\ln(4x + 1) - \ln(2x) = 3\)

6. Use a graphing utility to solve the equation \(\log_3(4x + 5) - \log_3 x = 2\)
7. Use a graphing utility to solve the equation \(\log(x^2 - 3) = \log(x + 5)\)
8. In example 3b, the solution to the log equation \(\log_2(3x + 8) + 1 = \log_3(10 - x)\) was found to be \(x \approx -1.87\). One student read this example, and wondered how the value of \(x\) could be negative, given that you cannot take a log of a negative number. How would you explain to this student why the solution is valid?

9. The data set below represents a hypothetical situation. You invest $2000 in a money market account, and you do not invest more money or withdraw any from the account.

<table>
<thead>
<tr>
<th>Time since you invested (in years)</th>
<th>Amount in account (dollars)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2000</td>
</tr>
<tr>
<td>2</td>
<td>2200</td>
</tr>
<tr>
<td>5</td>
<td>2500</td>
</tr>
<tr>
<td>10</td>
<td>3300</td>
</tr>
</tbody>
</table>

   a) Use a graphing utility to find an exponential model for the data.
b) Use your model to estimate the value of the account after the 8th year.
c) At this rate, much money would be in the account after 30 years?
d) Explain how your estimate in part (c) might be inaccurate. (What might happen after 20 years?)

10. The data set below represents the growth of a plant.

<table>
<thead>
<tr>
<th>Time since planting (days)</th>
<th>1</th>
<th>4</th>
<th>5</th>
<th>10</th>
<th>12</th>
<th>14</th>
</tr>
</thead>
<tbody>
<tr>
<td>Height of plant (inches)</td>
<td>.2</td>
<td>.5</td>
<td>.57</td>
<td>1.2</td>
<td>1.3</td>
<td>1.4</td>
</tr>
</tbody>
</table>

   a) Use a graphing utility to find a logarithmic equation to model the data.
b) Use your model to estimate the height of the plant after 15 days. Compare this estimate to the trend in the data.
c) Give an example of an \(x\) value for which the model does not make sense.

11. In the lesson, the equation \(\log(5 - x) + 1 = \log x\) was solved using a graph. Solve this equation algebraically in order to (a) verify the approximate solution found in the lesson and (b) give an exact solution.
Answers

1. \( x = \log_5 18 + 4 \) or \( x = \frac{\log 18}{\log 5} + 4 \)

2. \( x = \frac{-5 \log 7}{\log 4 - 3 \log 7} \)

3. \( x = 60 \)

4. \( x = 1 \)

5. \( x = \frac{1}{2e^3 - 4} \)

6. The function \( y = \log_3(4x + 5) - \log_3 x \) intersects the line \( y = 2 \) at the point \((1, 2)\).

7. The graphs intersect twice, giving 2 solutions: \( x \approx -2.37, x \approx 3.37 \).

8. The value of \( x \) can be negative as long as the argument of the log is positive. In this equation, the arguments are \( 3x + 8 \) and \( 10 - x \). Neither expression takes on a negative value for \( x \approx -1.87 \).

9. (a) \( y = 2045.405(1.042)^x \). (b) About \$2840. (c) About \$7003. (d) After that much time, you may decide to withdraw the money to spend or to invest in something with more potential growth.

10. (a) \( y = 0.0313 + .4780 \ln x \). (b) The model gives 1.33 inches. The data would suggest the plant is at least 1.4 inches tall. (c) The model does not make sense for negative \( x \) values. Also, at some point the plant could die. This reality puts an upper bound on \( x \).

11. Isolate \( x \):

\[
\begin{align*}
\log(5 - x) + 1 &= \log x \\
\log(5 - x) - \log x &= -1 \\
\log\left(\frac{5 - x}{x}\right) &= -1 \\
10^{-1} &= \frac{5 - x}{x} \\
0.1 &= \frac{5 - x}{x} \\
0.1x &= 5 - x \\
1.1x &= 5 \\
x &= \frac{5}{1.1} = \frac{50}{11} = \frac{46}{11} \\
x &= 4.18 \\
\end{align*}
\]
6.4 Compound Interest

1. You put $3500 in a bank account that earns 5.5% interest, compounded monthly. How much is in your account after 2 years? After 5 years?

2. You put $2000 in a bank account that earns 7% interest, compounded quarterly. How much is in your account after 10 years?

3. Solve an exponential equation in order to answer the question: given the investment in question #2, how many years will it take for the account to reach $10,000?

4. Use a graph to verify your answer to question #3.

5. Consider two investments:
   i. $2000, invested at 6% interest, compounded monthly
   ii. $3000, invested at 4.5% interest, compounded monthly

Use a graph to determine when the two investments have equal value.

6. You invest $3000 in an account that pays 6% interest, compounded monthly. How long does it take to double your investment?

7. Explain why the answer to #6 does not depend on the amount of the initial investment.

8. You invest $4,000 in an account that pays 3.2% interest, compounded continuously. What is the value of the account after 5 years?

9. You invest $6,000 in an account that pays 5% interest, compounded continuously. What is the value of the account after 10 years?

10. Consider the investment in question #8. How many years will it take the investment to reach $20,000?

Answers

1. After 2 years: $3905.99. 
   After 5 years: $4604.96.
2. $4003.19
3. Start with $2000 \left(1 + \frac{0.07}{4}\right)^{4t} = 10000$ and solve for $t$, $t = \frac{\ln 5}{4 \ln 1.0175} \approx 23.19$ years.
4. The functions cross at $x \approx 23.19$.
5. It takes about 27 years for the two investments to have the same value.
6. $t = \frac{\ln 2}{12 \ln 1.005} \approx 11.58$ years.
7. When solving for $t$, the 6000 is divided by 3000, resulting in a 2 on the left side of the equation. (hence the $\ln 2$). This would be the same, no matter what the initial investment was since the final amount is always twice as large as the initial investment.
8. $4694.03$
9. $9892.36$
10. It will take about 50 years.
6.5 Growth and Decay

1. The population of a town was 50,000 in 1980, and it grew to 70,000 by 1995.
   a) Write an exponential function to model the growth of the population.
   b) Use the function to estimate the population in 2010.
   c) What if the population growth was linear? Write a linear equation to model the population growth, and use it to estimate the population in 2010.

2. A telecommunications company began providing wireless service in 1994, and during that year the company had 1000 subscribers. By 2004, the company had 12,000 subscribers.
   a) Write an exponential function to model the situation
   b) Use the model to determine how long it will take for the company to reach 50,000 subscribers.

3. The population of a particular strain of bacteria triples every 8 hours.
   a) Write a general exponential function to model the bacteria growth.
   b) Use the model to determine how long it will take for a sample of bacteria to be 100 times its original population.
   c) Use a graph to verify your solution to part (b).

4. The half-life of acetaminophen is about 2 hours.
   a) If you take 650 mg of acetaminophen, how much will be left in your system after 7 hours?
   b) How long before there is less than 25 mg in your system?

5. The population of a city was 200,000 in 1991, and it decreased to 170,000 by 2001.
   a) Write an exponential function to model the decreasing population, and use the model to predict the population in 2008.
   b) Under what circumstances might the function cease to model the situation after a certain point in time?

6. Consider the following situation: you buy a large box of pens for the start of the school year, and after six weeks, \( \frac{1}{3} \) of the pens remain. After another six weeks, \( \frac{1}{3} \) of the remaining pens were remaining. If you continue this pattern, when will you only have 5% of the pens left?

7. Use Newton’s law of cooling \( T = T_s + (T_o - T_s)e^{-kt} \) to answer the question: you pour hot water into a mug to make tea. The temperature of the water is about 200 degrees. The surrounding temperature is about 75 degrees. You let the water cool for 5 minutes, and the temperature decreases to 160 degrees. What will the temperature be after 15 minutes?

8. The spread of a particular virus can be modeled with the logistic function \( f(x) = \frac{200}{1 + 600e^{-7.5x}} \), where \( x \) is the number of days the virus has been spreading, and \( f(x) \) represents the number of people who have the virus.
   a) How many people will be affected after 7 days?
   b) How many days will it take for the spread to be within one person of carrying capacity?
9. Consider again the situation in question #2: A telecommunications company began providing wireless service in 1994, and during that year the company had 1000 subscribers. By 2004, the company had 12,000 subscribers. If the company has 15,000 subscribers in 2005, and 16,000 in 2007, what type of model do you think should be used to model the situation? Use a graphing calculator to find a regression equation, and use the equation to predict the number of subscribers in 2010.

10. Compare exponential and logistic functions as tools for modeling growth. What do they have in common, and how do they differ?

Answers

1. (a) \( A(t) = 50,000e^{\frac{\ln(7/5)}{15}t} \), or \( A(t) = 50,000e^{0.02243t}. \) (Alternatively, \( A(t) = 50,000 \left(\frac{7}{5}\right)^{t/15}. \))

(b) The estimated population is 98,000, which is a difference of 8000 people or different by about 8% of the population predicted by the exponential model.

(c) \( f(t) = \frac{4000}{3}t + 50000. \) The pop. would be 90,000, which is different by about 9%.

2. (a) \( S(t) = 1000e^{\frac{\ln(12)}{10}t}. \) (Alternatively, \( S(t) = 1000(12)^{t/10} \)).

(b) \( t = \frac{10\ln 50}{\ln 12} \approx 15.74. \) Approximately, 15.74 years to reach 50,000 subscribers.

3. (a) \( A(t) = A_o(3)^{t/8} \)

(b) \( t = \frac{16}{\ln 3} \approx 33.53. \) It takes approximately 33.53 hours (about 1 day, 9 hours, 32 minutes) to reach 100 times its original population.

(c) Use the 'intersect' feature for \( Y_1 = 100t \) and \( Y_2 = 3^{x/8}, \) which intersect at approximately \( X = 33.53. \)

4. (a) About 57.45 mg

(b) About 9.4 hours.

5. (a) \( P(t) = 20000e^{\left(\frac{\ln 85}{70}\right)t} \) or \( P(t) = 20000e^{0.4443t}. \) \( P(17) \approx 151720. \) (Alternatively \( P(t) = 20000(0.85)^{t/10} \)) The estimated population in 2008 is 151,720.

(b) If the economy or other factors change, the population might begin to increase, or the rate of decrease could change as well.

6. \( t = \frac{6\ln(0.05)}{\ln(1/3)} \approx 16 \) weeks.

7. About 114 degrees. (Hint: Determine \( k \) first in the model \( T(x) = 75 + 125e^{-kx}, \) knowing the temperature is 160 degrees at 5 minutes.)

8. (a) About 482 people.

(b) After 19 days, over 1999 people have the virus.

9. The graph (scatterplot) indicates a logistic model. \( f(t) \approx \frac{17952}{1+21.45e^{-0.377x}} \) gives 17952 subscribers in 2010.

Both types of functions model fast increase in growth, but the logistic model shows the growth slowing down after some point, with some upper bound on the quantity in question. (Many people argue that logistic growth is more realistic.)
6.6 Logarithmic Scales

1. Verify that a sound of intensity 1000 times that of a sound of 0 dB corresponds to 30 dB.

2. Calculate the decibel level of a sound with intensity $10^{-8}$ W/m$^2$.

3. Calculate the intensity of a sound if the decibel level is 25.

4. The 2004 Indian Ocean earthquake was recorded to have a magnitude of about 9.5. In 1960, an earthquake in Chile was recorded to have a magnitude of 9.1. How much stronger was the 2004 Indian Ocean quake?

5. The concentration of H$^+$ in pure water is $110^{-7}$ moles per liter. What is the pH?

6. The pH of normal human blood is 7.4. What is the concentration of H$^+$?

Answers

1. $\text{dB} = 10 \log \left( \frac{100 \times 10^{-12}}{10^{-12}} \right)$
   $= 10 \log(100) = 10(3) = 30.$

2. $\text{dB} = 10 \log \left( \frac{10^{-8}}{10^{-12}} \right)$
   $= 10 \log(10000) = 10(4) = 40.$ This sound level is 40 decibels.

3. $10^{-9.5}$. Approximately $3.16 \times 10^{-10}$ W/m$^2$, or alternatively, $10^{0.5}$ W/m$^2$.

4. $10^{0.4} \approx 2.5$. The Indian Ocean earthquake was 2.5 times stronger than the Chilean earthquake.

5. The pH is 7.

6. $10^{-7.4} \approx 3.98 \times 10^{-8}$. The concentration of H$^+$ is approximately $3.98 \times 10^{-8}$ moles per liter, or alternatively $10^{-7.4}$ moles per liter.
